#### Preface

The following document was developed to facilitate the use of agricolae package in R, it is understood that the user knows the statistical methodology for the design and analysis of experiments and through the use of the functions programmed in agricolae facilitate the generation of the field book experimental design and their analysis. The first part document describes the use of graph.freq role is complementary to the *hist* function of R functions to facilitate the collection of statistics and frequency table, statistics or grouped data histogram based training grouped data and graphics as frequency polygon or ogive; second part is the development of experimental plans and numbering of the units as used in an agricultural experiment; a third part corresponding to the comparative tests and finally provides agricolae miscellaneous additional functions applied in agricultural research and stability functions, soil consistency, late blight simulation and others.

#### 1 Introduction

The package agricolae offers a broad functionality in the design of experiments, especially for experiments in agriculture and improvements of plants, which can also be used for other purposes. It contains the following designs: lattice, alpha, cyclic, balanced incomplete block designs, complete randomized blocks, Latin, Graeco-Latin, augmented block designs, split plot and strip plot. It also has several procedures of experimental data analysis, such as the comparisons of treatments of Waller-Duncan, Bonferroni, Duncan, Student-Newman-Keuls, Scheffe, or the classic LSD and Tukey; and non-parametric comparisons, such as Kruskal-Wallis, Friedman, Durbin, Median and Waerden, stability analysis, and other procedures applied in genetics, as well as procedures in biodiversity and descriptive statistics. reference [4]

#### 1.1 Installation

The main program of  $\mathbf{R}$  should be already installed in the platform of your computer (Windows, Linux or MAC). If it is not installed yet, you can download it from the R project (www.r-project.org) of a repository CRAN. Reference [14]

> install.packages("agricolae") Once the agricolae package is installed, it needs to be made accessible to the current R session by the command:

> library(agricolae)

For online help facilities or the details of a particular command (such as the function waller.test) you can type:

```
> help(package="agricolae")
> help(waller.test)
```

For a complete functionality, agricolae requires other packages.

MASS: for the generalized inverse used in the function PBIB.test

**nlme:** for the methods REML and LM in *PBIB.test* **klaR:** for the function *triplot* used in the function *AMMI* 

Cluster: for the use of the function consensus

**spdep:** for the between genotypes spatial relation in biplot of the function AMMI algDesign: for the balanced incomplete block design design.bib

#### 1.2 Use in R

Since **agricolae** is a package of functions, these are operational when they are called directly from the console of  $\mathbf{R}$  and are integrated to all the base functions of  $\mathbf{R}$ . The following orders are frequent:

```
> detach(package:agricolae) # detach package agricole
> library(agricolae) # Load the package to the memory
> designs<-apropos("design")</pre>
> print(designs[substr(designs,1,6)=="design"], row.names=FALSE)
 [1] "design.ab"
                       "design.alpha"
                                        "design.bib"
                       "design.cyclic"
 [4] "design.crd"
                                        "design.dau"
 [7] "design.graeco"
                       "design.lattice" "design.lsd"
[10] "design.rcbd"
                       "design.split"
                                        "design.strip"
[13] "design.youden"
```

For the use of symbols that do not appear in the keyboard in Spanish, such as:

```
\tilde{}, [, ], &, \hat{}, |. <, >, {, }, \% or others, use the table ASCII code.
```

> library(agricolae) # Load the package to the memory:

In order to continue with the command line, do not forget to close the open windows with any R order. For help:

```
help(graph.freq)
? (graph.freq)
str(normal.freq)
example(join.freq)
```

#### 1.3 Data set in agricolae

```
> A<-as.data.frame(data(package="agricolae")$results[,3:4])
> A[,2]<-paste(substr(A[,2],1,35),"..",sep=".")
> head(A)
```

```

#### 2 Descriptive statistics

The package **agricolae** provides some complementary functions to the  $\mathbf{R}$  program, specifically for the management of the histogram and function hist.

#### 2.1 Histogram

The histogram is constructed with the function *graph.freq* and is associated to other functions: *polygon.freq*, *table.freq*, *stat.freq*. See Figures: 1, 2 and 3 for more details.

Example. Data generated in  $\mathbf{R}$  . (students' weight).

```
> weight<-c(68, 53, 69.5, 55, 71, 63, 76.5, 65.5, 69, 75, 76, 57, 70.5, 71.5, 56, 81.5,
             69, 59, 67.5, 61, 68, 59.5, 56.5, 73, 61, 72.5, 71.5, 59.5, 74.5, 63)
> print(summary(weight))
  Min. 1st Qu. Median
                           Mean 3rd Qu.
                                           Max.
  53.00
         59.88
                  68.00
                          66.45
                                  71.50
                                          81.50
> par(mfrow=c(1,2), mar=c(4,3,0,1), cex=0.6)
> h1<- graph.freq(weight,col="yellow",frequency=1,las=2,xlab="h1")
> h2<- graph.freq (weight, frequency =2, axes= FALSE,las=2,xlab="h2")
> polygon.freq(h2, col="blue", lwd=2, frequency =2)
> TIC<- h2$breaks[2]- h2$breaks[1]
> axis(1,c(h2$mids[1]-TIC, h2$mids, h2$mids[6]+TIC),cex=0.6)
> axis(2, cex=0.6,las=1)
```

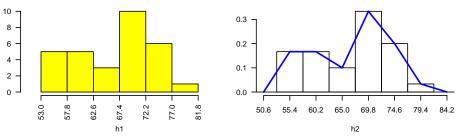

Figure 1: Absolute and relative frequency with polygon.

#### 2.2 Statistics and Frequency tables

Statistics: mean, median, mode and standard deviation of the grouped data.

> stat.freq(h1)

#### \$variance

[1] 51.37655

#### \$mean

[1] 66.6

#### \$median

[1] 68.36

\$mode

# [- -] mode [1,] 67.4 72.2 70.45455

Frequency tables: Use table.freq, stat.freq and summary

The table.freq is equal to summary()

Limits class: Lower and Upper

Class point: **Main** Frequency: **Frequency** 

Percentage frequency: Percentage

Cumulative frequency:  $\mathbf{CF}$ 

Cumulative percentage frequency: CPF

> print(summary(h1),row.names=FALSE)

Lower	Upper	Main	Frequency	Percentage	CF	CPF
53.0	57.8	55.4	5	16.7	5	16.7
57.8	62.6	60.2	5	16.7	10	33.3
62.6	67.4	65.0	3	10.0	13	43.3
67.4	72.2	69.8	10	33.3	23	76.7
72.2	77.0	74.6	6	20.0	29	96.7
77.0	81.8	79.4	1	3.3	30	100.0

#### 2.3 Histogram manipulation functions

You can extract information from a histogram such as class intervals *intervals.freq*, attract new intervals with the *sturges.freq* function or to join classes with *join.freq* function. It is also possible to reproduce the graph with the same creator *graph.freq* or function *plot* and overlay normal function with *normal.freq* be it a histogram in absolute scale, relative or density. The following examples illustrates these properties.

```
> sturges.freq(weight)
```

\$maximum

[1] 81.5

\$minimum

[1] 53

\$amplitude

[1] 29

\$classes

[1] 6

\$interval

[1] 4.8

\$breaks

[1] 53.0 57.8 62.6 67.4 72.2 77.0 81.8

```
> intervals.freq(h1)
     lower upper
      53.0 57.8
[1,]
[2,]
      57.8

          0.3
                                               0.4
          0.2
                                               0.2
          0.1
          0.0
                                               0.0
                  53.0
                             67.4 72.2 77.0 81.8
                                                                  72.2 77.0 81.8
                                                  53.0
```

Figure 2: Join frequency and relative frequency with normal and Ogive.

#### 2.4 hist() and graph.freq() based on grouped data

The hist and graph.freq have the same characteristics, only f2 allows build histogram from grouped data.

```
0-10 (3)
10-20 (8)
20-30 (15)
30-40 (18)
40-50 (6)

> par(mfrow=c(1,2),mar=c(4,3,2,1),cex=0.6)
> h4<-hist(weight,xlab="Classes (h4)")
> table.freq(h4)
> # this is possible
> # hh<-graph.freq(h4,plot=FALSE)
> # summary(hh)
> # new class
> classes <- c(0, 10, 20, 30, 40, 50)
> freq <- c(3, 8, 15, 18, 6)
> h5 <- graph.freq(classes,counts=freq, xlab="Classes (h5)",main="Histogram grouped data")
```

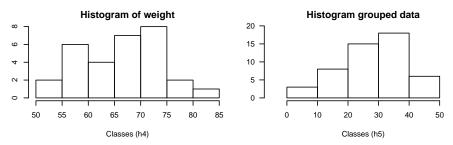

Figure 3: hist() function and histogram defined class

> print(summary(h5),row.names=FALSE)

Lower	Upper	Main	Frequency	${\tt Percentage}$	CF	CPF
0	10	5	3	6	3	6
10	20	15	8	16	11	22
20	30	25	15	30	26	52
30	40	35	18	36	44	88
40	50	45	6	12	50	100

### 3 Experiment designs

The package **agricolae** presents special functions for the creation of the field book for experimental designs. Due to the random generation, this package is quite used in agricultural research.

For this generation, certain parameters are required, as for example the name of each treatment, the number of repetitions, and others, according to the design references [1, 9, 10, 11]. There are other parameters of random generation, as the seed to reproduce the same random generation or the generation method (See the reference manual of **agricolae**.

http://cran.at.r-project.org/web/packages/agricolae/agricolae.pdf

#### Important parameters in the generation of design:

series: A constant that is used to set numerical tag blocks, eg number = 2, the labels will be: 101, 102, for the first row or block, 201, 202, for the following, in the case of completely randomized design, the numbering is sequencial.

design: Some features of the design requested agricolae be applied specifically to design.ab(factorial) or design.split (split plot) and their possible values are: "rcbd", "crd" and "lsd".

**seed:** The seed for the random generation and its value is any real value, if the value is zero, it has no reproducible generation, in this case copy of value of the outdesign\$parameters.

**kinds:** the random generation method, by default "Super-Duper".

first: For some designs is not required random the first repetition, especially in the block design, if you want to switch to random, change to TRUE.

randomization: TRUE or FALSE. If false, randomization is not performed

#### Output design:

**parameters:** the input to generation design, include the seed to generation random, if seed=0, the program generate one value and it is possible reproduce the design.

book: field book

statistics: the information statistics the design for example efficiency index, number of treatments.

**sketch:** distribution of treatments in the field.

#### The enumeration of the plots

zigzag is a function that allows you to place the numbering of the plots in the direction of serpentine: The zigzag is output generated by one design: blocks, Latin square, graeco, split plot, strip plot, into blocks factorial, balanced incomplete block, cyclic lattice, alpha and augmented blocks.

fieldbook: output zigzag, contain field book.

#### 3.1 Completely randomized design

They only require the names of the treatments and the number of their repetitions and its parameters are:

```
> str(design.crd)
function (trt, r, serie = 2, seed = 0, kinds = "Super-Duper",
    randomization = TRUE)
> trt <- c("A", "B", "C")
> repeticion \leftarrow c(4, 3, 4)
> outdesign <- design.crd(trt,r=repeticion,seed=777,serie=0)</pre>
> book1 <- outdesign$book
> head(book1)
 plots r trt
1
      1 1 B
      2 1
2
            Α
      3 2
            Α
      4 1
            C
```

```
5 5 2 C
6 6 3 A
```

Excel:write.csv(book1,"book1.csv",row.names=FALSE)

#### 3.2 Randomized complete block design

They require the names of the treatments and the number of blocks and its parameters are:

```
> str(design.rcbd)
function (trt, r, serie = 2, seed = 0, kinds = "Super-Duper",
    first = TRUE, continue = FALSE, randomization = TRUE)
> trt <- c("A", "B", "C", "D", "E")
> repeticion <- 4
> outdesign <- design.rcbd(trt,r=repeticion, seed=-513, serie=2)
> # book2 <- outdesign$book</pre>
> book2<- zigzag(outdesign) # zigzag numeration
> print(outdesign$sketch)
     [,1] [,2] [,3] [,4] [,5]
[1,] "D" "B" "C" "E" "A"
[2,] "E" "A" "D" "B"
                        "C"
[3,] "E" "D"
              "B"
                   "A"
                        "C"
[4,] "A" "E"
              "C"
                   "B"
                        "ח"
> print(matrix(book2[,1],byrow = TRUE, ncol = 5))
     [,1] [,2] [,3] [,4] [,5]
[1,] 101 102 103 104 105
[2,] 205
          204 203
                    202 201
[3,] 301 302 303
                    304 305
[4,]
     405 404 403 402 401
```

#### 3.3 Latin square design

They require the names of the treatments and its parameters are:

```
> str(design.lsd)

function (trt, serie = 2, seed = 0, kinds = "Super-Duper",
    first = TRUE, randomization = TRUE)

> trt <- c("A", "B", "C", "D")
> outdesign <- design.lsd(trt, seed=543, serie=2)
> print(outdesign$sketch)
```

```
[,1] [,2] [,3] [,4]
[1,] "C" "A"
             "B"
                  "D"
[2,] "D" "B"
                  "A"
             "C"
[3,] "B" "D"
             "A" "C"
[4,] "A" "C" "D" "B"
```

#### Serpentine enumeration:

```
> book <- zigzag(outdesign)</pre>
> print(matrix(book[,1],byrow = TRUE, ncol = 4))

#### Graeco-Latin designs 3.4

They require the names of the treatments of each factor of study and its parameters are:

```
> str(design.graeco)
function (trt1, trt2, serie = 2, seed = 0, kinds = "Super-Duper",
    randomization = TRUE)
> trt1 <- c("A", "B", "C", "D")
> trt2 <- 1:4
> outdesign <- design.graeco(trt1,trt2, seed=543, serie=2)
> print(outdesign$sketch)
     [,1] [,2] [,3] [,4]
[1,] "A 1" "D 4" "B 3" "C 2"
[2,] "D 3" "A 2" "C 1" "B 4"
[3,] "B 2" "C 3" "A 4" "D 1"
[4,] "C 4" "B 1" "D 2" "A 3"
Serpentine enumeration:
> book <- zigzag(outdesign)</pre>
```

```
> print(matrix(book[,1],byrow = TRUE, ncol = 4))
    [,1] [,2] [,3] [,4]

#### 3.6 Balanced Incomplete Block Designs

They require the names of the treatments and the size of the block and its parameters are:

```
> str(design.bib)
function (trt, k, r = NULL, serie = 2, seed = 0, kinds = "Super-Duper",
   maxRep = 20, randomization = TRUE)
> trt <- c("A", "B", "C", "D", "E")
> outdesign <- design.bib(trt,k, seed=543, serie=2)</pre>
Parameters BIB
_____
       : 3
Lambda
treatmeans : 5
Block size : 4

> book5 <- outdesign$book
> outdesign$statistics
      lambda treatmeans blockSize blocks r Efficiency
values
          3
                      5
                            4
                                   5 4
                                              0.9375
> outdesign$parameters
$design
[1] "bib"
$trt
[1] "A" "B" "C" "D" "E"
$k
[1] 4
```

[1] 2

#### \$seed

[1] 543

#### \$kinds

[1] "Super-Duper"

According to the produced information, they are five blocks of size 4, being the matrix:

#### > outdesign\$sketch

```
[,1] [,2] [,3] [,4]
[1,] "D"
                       "C"
           "B"
                 "E"
[2,] "B"
           "A"
                 "C"
                       "E"
[3,] "D"
           "C"
                 "E"
                       "A"
           "A"
                       "C"
[4,] "D"
                 "B"
[5,] "B"
           "D"
                 "E"
                       "A"
```

It can be observed that the treatments have four repetitions. The parameter lambda has three repetitions, which means that a couple of treatments are together on three occasions. For example, B and E are found in the blocks I, II and V.

#### Serpentine enumeration:

                 503
                       504
```

#### 3.7 Cyclic designs

They require the names of the treatments, the size of the block and the number of repetitions. This design is used for 6 to 30 treatments. The repetitions are a multiple of the size of the block; if they are six treatments and the size is 3, then the repetitions can be 6, 9, 12, etc. and its parameters are:

```
> str(design.cyclic)

function (trt, k, r, serie = 2, rowcol = FALSE, seed = 0,
    kinds = "Super-Duper", randomization = TRUE)

> trt <- c("A", "B", "C", "D", "E", "F" )
> outdesign <- design.cyclic(trt,k=3, r=6, seed=543, serie=2)</pre>
```

```

#### 3.9 Alpha designs

These designs are generated by the alpha arrangements reference [12]. They are similar to the lattice designs, but the tables are rectangular, with s blocks x k treatments. The number of treatments should be equal to s\*k and all the experimental units, r\*s\*k and its parameters are:

```
> str(design.alpha)
function (trt, k, r, serie = 2, seed = 0, kinds = "Super-Duper",
    randomization = TRUE)
> trt <- letters[1:15]
> outdesign <- design.alpha(trt,k=3,r=2,seed=543)

#### 3.10 Augmented block designs

These are designs for two types of treatments: the control treatments (common) and the increased treatments. The common treatments are applied in complete randomized blocks, and the increased treatments, at random. Each treatment should be applied in any block once only. It is understood that the common treatments are of a greater interest; the standard error of the difference is much smaller than when between two increased ones in different blocks. The function design.dau() achieves this purpose and its parameters are:

```
> str(design.dau)
function (trt1, trt2, r, serie = 2, seed = 0, kinds = "Super-Duper",
   name = "trt", randomization = TRUE)
> rm(list=ls())
> trt1 <- c("A", "B", "C", "D")
> trt2 <- c("t", "u", "v", "w", "x", "v", "z")
> outdesign <- design.dau(trt1, trt2, r=5, seed=543, serie=2)
> book9 <- outdesign$book
> attach(book9)
> by(trt, block,as.character)
[1] "D" "C" "A" "u" "B" "t"
block: 2
[1] "D" "z" "C" "A" "v" "B"

      1 t
```

For augmented ompletely randomized design, use the function design.crd().

#### 3.11 Split plot designs

These designs have two factors, one is applied in plots and is defined as A in a randomized complete block design; and a second factor, which is applied in the subplots of each plot applied at random. The function design.split() permits to find the experimental plan for this design and its parameters are:

```
> str(design.split)
function (trt1, trt2, r = NULL, design = c("rcbd",
    "crd", "lsd"), serie = 2, seed = 0, kinds = "Super-Duper",
    first = TRUE, randomization = TRUE)
Aplication
> trt1<-c("A","B","C","D")
> trt2<-c("a", "b", "c")
> outdesign <-design.split(trt1,trt2,r=3,serie=2,seed=543)
> book10 <- outdesign$book

#### 3.12Strip-plot designs

These designs are used when there are two types of treatments (factors) and are applied separately in large plots, called bands, in a vertical and horizontal direction of the block, obtaining the divided blocks. Each block constitutes a repetition and its parameters are:

```
> str(design.strip)
function (trt1, trt2, r, serie = 2, seed = 0, kinds = "Super-Duper",
    randomization = TRUE)
```

#### Aplication

```
> trt1<-c("A", "B", "C", "D")
> trt2<-c("a","b","c")
> outdesign <-design.strip(trt1,trt2,r=3,serie=2,seed=543)
> book11 <- outdesign$book</pre>

#### 3.13 Factorial

The full factorial of n factors applied to an experimental design (CRD, RCBD and LSD) is common and this procedure in **agricolae** applies the factorial to one of these three designs and its parameters are:

To generate the factorial, you need to create a vector of levels of each factor, the method automatically generates up to 25 factors and "r" repetitions.

```
> trt <- c (4,2,3) # three factors with 4,2 and 3 levels.
```

to crd and rcbd designs, it is necessary to value "r" as the number of repetitions, this can be a vector if unequal to equal or constant repetition (recommended).

```
> trt<-c(3,2) # factorial 3x2
> outdesign <-design.ab(trt, r=3, serie=2)</pre>
> book12 <- outdesign$book</pre>
> head(book12) # print of the field book
 plots block A B

#### 4 Multiple comparisons

For the analyses, the following functions of **agricolae** are used: LSD.test, HSD.test, duncan.test, scheffe.test, waller.test, SNK.test, REGW.test reference [17, 6] and durbin.test, kruskal, friedman, waerden.test and Median.test reference [2].

For every statistical analysis, the data should be organized in columns. For the demonstration, the agricolae database will be used.

The *sweetpotato* data correspond to a completely random experiment in field with plots of 50 sweet potato plants, subjected to the virus effect and to a control without virus (See the reference manual of the package).

```
> data(sweetpotato)
> model<-aov(yield~virus, data=sweetpotato)
> cv.model(model)

[1] 17.1666
> attach(sweetpotato)
> mean(yield)

[1] 27.625
> detach(sweetpotato)

Model parameters: Degrees of freedom and variance of the error:
```

> df<-df.residual(model)
> MSerror<-deviance(model)/df</pre>

#### 4.1 The Least Significant Difference (LSD)

It includes the multiple comparison through the method of the minimum significant difference (Least Significant Difference), reference [17].

```
> # comparison <- LSD.test(yield,virus,df,MSerror)</pre>
> LSD.test(model, "virus",console=TRUE)
Study: model ~ "virus"
LSD t Test for yield
Mean Square Error: 22.48917
virus, means and individual (95 %) CI

```

Other comparison tests can be applied, such as duncan, Student-Newman-Keuls, tukey and waller-duncan

For Duncan, use the function duncan.test; for Student-Newman-Keuls, the function SNK.test; for Tukey, the function HSD.test(); for Scheffe, the function scheffe.test; and for Waller-Duncan, the function waller.test. The parameters are the same. Waller also requires the value of F-calculated of the ANOVA treatments. If the model is used as a parameter, this is no longer necessary.

#### 4.3 Duncan's New Multiple-Range Test

#### 4.7 Waller-Duncan's Bayesian K-Ratio T-Test

In 1975, Duncan continued the multiple comparison procedures, introducing the criterion of minimizing both experimental errors; for this, he used the Bayes' theorem, obtaining one new test called Waller-Duncan reference [17]

```
> # variance analysis:
> anova(model)
Analysis of Variance Table
Response: yield

## 4.11 Partially Balanced Incomplete Blocks

The function *PBIB.test*, reference [7], can be used for the lattice and alpha designs.

Consider the following case: Construct the alpha design with 30 treatments, 2 repetitions, and a block size equal to 3.

The generated plan is plan\$book.

Suppose that the corresponding observation to each experimental unit is:

```
> yield <-c(5,2,7,6,4,9,7,6,7,9,6,2,1,1,3,2,4,6,7,9,8,7,6,4,3,2,2,1,1,
+ 2,1,1,2,4,5,6,7,8,6,5,4,3,1,1,2,5,4,2,7,6,6,5,6,4,5,7,6,5,5,4)</pre>
```

The data table is constructed for the analysis. In theory, it is presumed that a design is applied and the experiment is carried out; subsequently, the study variables are observed from each experimental unit.

```
> data<-data.frame(plan$book,yield)</pre>
```

- > rm(yield,Genotype)

# 5 Non-parametric comparisons

The functions for non-parametric multiple comparisons included in **agricolae** are: kruskal, waerden.test, friedman and durbin.test, reference [2].

The function kruskal is used for N samples (N>2), populations or data coming from a completely random experiment (populations = treatments).

The function waerden.test, similar to kruskal-wallis, uses a normal score instead of ranges as kruskal

The function *friedman* is used for organoleptic evaluations of different products, made by judges (every judge evaluates all the products). It can also be used for the analysis of treatments of the randomized complete block design, where the response cannot be treated through the analysis of variance.

The function *durbin.test* for the analysis of balanced incomplete block designs is very used for sampling tests, where the judges only evaluate a part of the treatments.

Montgomery book data, reference [11]. Included in the agricolae package

```
$ observation: int 83 91 94 89 89 96 91 92 90 91 ...
$ rx : num 11 23 28.5 17 17 31.5 23 26 19.5 23 ...
```

For the examples, the agricolae package data will be used

#### 5.1 Kruskal-Wallis

It makes the multiple comparison with Kruskal-Wallis. The parameters by default are alpha = 0.05.

```
> str(kruskal)
function (y, trt, alpha = 0.05, p.adj = c("none", "holm",
    "hochberg", "bonferroni", "BH", "BY", "fdr"), group = TRUE,
    main = NULL, console = FALSE)

# 6 Graphics of the multiple comparison

The results of a comparison can be graphically seen with the functions bar.group and bar.err.

### 6.1 bar.group

A function to plot horizontal or vertical bar, where the letters of groups of treatments is expressed. The function applies to all functions comparison treatments. Each object must use the group object previously generated by comparative function in indicating that group = TRUE. example:

```
> # model <-aov (yield ~ fertilizer, data = field)
> # out <-LSD.test (model, "fertilizer", group = TRUE)
> # bar.group (out $ group)
> str(bar.group)

function (x, horiz = FALSE, ...)
```

The found object of one comparison is the entry for these functions, see Figure 4. The objects outHSD and outWaller are used in the following exercise: outHSD, for the functions bar.group and bar.err outWaller, for the function bar.err

#### 6.2 bar.err

A function to plot horizontal or vertical bar, where the variation of the error is expressed in every treatments. The function applies to all functions comparison treatments. Each object must use the means object previously generated by the comparison function, see Figure 4

```
> # model <-aov (yield ~ fertilizer, data = field)
> # out <-LSD.test (model, "fertilizer", group = TRUE)
> # bar.err(out$means)
> str(bar.err)
```

```
function (x, variation = c("SE", "SD", "range"), horiz = FALSE,
    bar = TRUE, ...)

variation SE: Standard error
SD: standard deviation
range: max-min)

> par(mfrow=c(1,2),mar=c(3,3,2,0),cex=0.7)
> c1<-colors()[480]; c2=colors()[65]; c3=colors()[15]; c4=colors()[140]
> G1<-bar.group(outHSD$groups, ylim=c(0,45), main="Tukey\nG1",col=c1,las=1)
> # G2<-bar.group(outHSD$groups, horiz=T, xlim=c(0,45), main="Tukey\nG2",col=c2,las=1)
> # G3<-bar.err(outWaller$means, variation="range",ylim=c(0,45), col=c3,main="Range\nG3",las=1)
> G4<-bar.err(outWaller$means, horiz=T, xlim=c(0,45), col=c4, variation="SE",
+ main="Standard error \nG4",las=1)</pre>
```

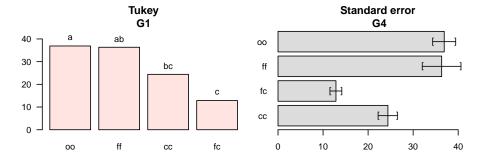

Figure 4: Comparison between treatments

```
> par(mfrow=c(2,2),cex=0.7,mar=c(3.5,1.5,3,0))
> C1<-bar.err(modelPBIB$means[1:7, ], ylim=c(0,9), col=0, main="C1",
+ variation="range",border=3,las=2)
> C2<-bar.err(modelPBIB$means[8:15,], ylim=c(0,9), col=0, main="C2",
+ variation="range", border =4,las=2)
> # Others graphic
> C3<-bar.err(modelPBIB$means[16:22,], ylim=c(0,9), col=0, main="C3",
+ variation="range",border =2,las=2)
> C4<-bar.err(modelPBIB$means[23:30,], ylim=c(0,9), col=0, main="C4",
+ variation="range", border =6,las=2)
> # Lattice graphics
> par(mar=c(2.5,2.5,1,0),cex=0.6)
> bar.group(modelLattice$group,ylim=c(0,55),density=10,las=1)
```

### 6.3 diffograph

It plots bars of the averages of treatments to compare. It uses the objects generated by a procedure of comparison like LSD (Fisher), duncan, Tukey (HSD), Student Newman Keul (SNK), Scheffe, Ryan, Einot and Gabriel and Welsch (REGW), Kruskal Wallis, Friedman and Waerden. Reference [6], see Figure 6

```
> # function (x, main = NULL, color1 = "red", color2 = "blue",
> # color3 = "black", cex.axis = 0.8, las = 1, pch = 20,
> # bty = "l", cex = 0.8, lwd = 1, xlab = "", ylab = "",
> # ...)
> # model : yield ~ virus
> # Important group=FALSE
> x<-HSD.test(model, "virus", group=FALSE)
> diffograph(x,cex.axis=0.9,xlab="Yield",ylab="Yield",cex=0.9)
```

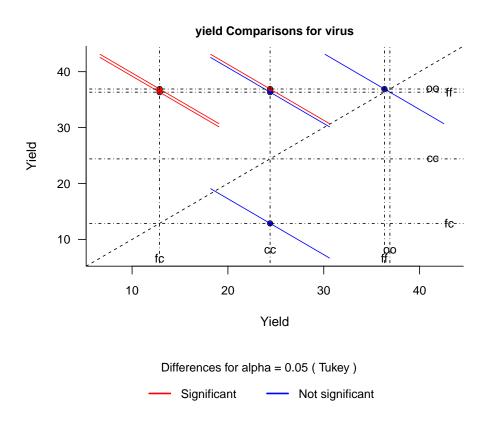

Figure 5: Mean-Mean scatter plot representation of the Tukey method

# 7 Stability Analysis

In agricolae there are two methods for the study of stability and the AMMI model. These are: a parametric model for a simultaneous selection in yield and stability "SHUKLA'S STABILITY VARIANCE AND KANG'S", reference [8] and a non-parametric method of Haynes, based on the data range.

## 7.1 Parametric Stability

Use the parametric model, function stability.par.

Prepare a data table where the rows and the columns are the genotypes and the environments, respectively. The data should correspond to yield averages or to another measured variable. Determine the variance of the common error for all the environments and the number of repetitions that was evaluated for every genotype. If the repetitions are different, find a harmonious average that will represent the set. Finally, assign a name to each row that will represent the genotype. Reference [8] We will consider five environments in the following example:

```
> options(digit=2)
> v1 <- c(10.2,8.8,8.8,9.3,9.6,7.2,8.4,9.6,7.9,10,9.3,8.0,10.1,9.4,10.8,6.3,7.4)
> v2 <- c(7,7.8,7.0,6.9,7,8.3,7.4,6.5,6.8,7.9,7.3,6.8,8.1,7.1,7.1,6.4,4.1)
> v3 <- c(5.3,4.4,5.3,4.4,5.5,4.6,6.2,6.0,6.5,5.3,5.7,4.4,4.2,5.6,5.8,3.9,3.8)
> v4 <- c(7.8,5.9,7.3,5.9,7.8,6.3,7.9,7.5,7.6,5.4,5.6,7.8,6.5,8.1,7.5,5.0,5.4)
> v5 <- c(9,9.2,8.8,10.6,8.3,9.3,9.6,8.8,7.9, 9.1,7.7,9.5,9.4,9.4,10.3,8.8,8.7)</pre>
```

For 17 genotypes, the identification is made by letters.

```
> study <- data.frame(v1, v2, v3, v4, v5)
> rownames(study) <- LETTERS[1:17]</pre>
```

An error variance of 2 and 4 repetitions is assumed.

#### Analysis

```
> output <- stability.par(study, rep=4, MSerror=2)
> names(output)

[1] "analysis" "statistics" "stability"
```

   5.88
                     -3
                              -2 3.598500
                                                          -2
```

The selected genotypes are: A, C, E, G, H, J, M, N and O. These genotypes have a higher yield and a lower variation. to see output\$analysis, the interaction is significant.

If for example there is an environmental index, it can be added as a covariate. For this case, the altitude of the localities is included.

```
> altitude<-c(1200, 1300, 800, 1600, 2400)
> stability <- stability.par(study,rep=4,MSerror=2, cova=TRUE, name.cov= "altitude",
+ file.cov=altitude)</pre>
```

## 7.2 Non-parametric Stability

For non-parametric stability, the function in 'agricolae' is stability.nonpar(). The names of the genotypes should be included in the first column, and in the other columns, the response by environments. Reference [5]

#### Analysis

### **7.3** AMMI

The model AMMI uses the biplot constructed through the principal components generated by the interaction environment-genotype. If there is such interaction, the percentage of the two principal components would explain more than the 50% of the total variation; in such case, the biplot would be a good alternative to study the interaction environment-genotype. Reference [3]

The data for AMMI should come from similar experiments conducted in different environments. Homogeneity of variance of the experimental error, produced in the different environments, is required. The analysis is done by combining the experiments.

The data can be organized in columns, thus: environment, genotype, repetition, and variable.

The data can also be the averages of the genotypes in each environment, but it is necessary to consider a harmonious average for the repetitions and a common variance of the error. The data should be organized in columns: environment, genotype, and variable.

When performing AMMI, this generates the Biplot, Triplot and Influence graphics, see Figures ?? For the application, we consider the data used in the example of parametric stability (study):

```

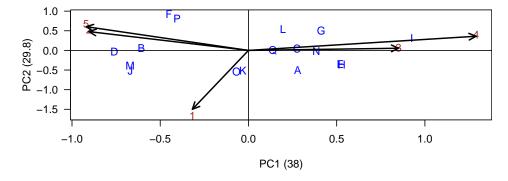

Figure 6: Biplot

In this case, the interaction is significant. The first two components explain 67.8 %; then the biplot can provide information about the interaction genotype-environment. With the triplot, 90.3% would be explained.

To triplot require klaR package. in R execute:

```
plot(model,type=2,las=1)
```

To Influence graphics genotype require spdep package, in R execute:

plot(model,type=3,las=1)

## 7.4 AMMI index and yield stability

# 8 Special functions

## 8.1 Consensus of dendrogram

Consensus is the degree or similarity of the vertexes of a tree regarding its branches of the constructed dendrogram. The function to apply is consensus().

The data correspond to a table, with the name of the individuals and the variables in the rows and columns respectively. For the demonstration, we will use the "pamCIP" data of 'agricolae', which correspond to molecular markers of 43 entries of a germplasm bank (rows) and 107 markers (columns).

The program identifies duplicates in the rows and can operate in both cases. The result is a dendrogram, in which the consensus percentage is included, see Figure 7.

When the dendrogram is complex, it is convenient to extract part of it with the function hcut(), see Figure 8.

The obtained object "output" contains information about the process:

```
> names(output)
```

```
[1] "table.dend" "dendrogram" "duplicates"
```

### Construct a classic dendrogram, execute procedure in R

use the previous result 'output'

```
> dend <- as.dendrogram(output$dendrogram)
> data <- output$table.dend
> head(output$table.dend)
```

```

Duplicates: 18

New data : 25 Records

#### Consensus hclust

Method distance: binary
Method cluster : complete
rows and cols : 25 107

n-bootstrap : 5

Run time : 0.740042 secs

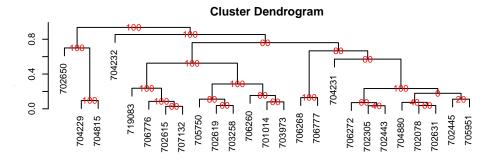

Figure 7: Dendrogram, production by consensus

> par(cex=0.6,mar=c(3,3,1.5,0))
> out1<- hcut(output,h=0.4,group=8,type="t",edgePar = list(lty=1:2, col=colors()[c(42,84)]),
+ main="group 8" ,col.text="blue",cex.text=1,las=1)</pre>

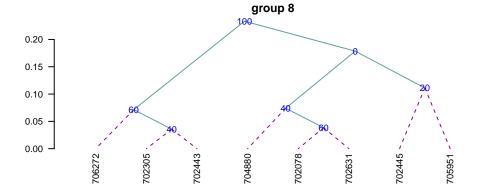

Figure 8: Dendrogram, production by hcut()

### 8.2 Montecarlo

It is a method for generating random numbers of an unknown distribution. It uses a data set and, through the cumulative behavior of its relative frequency, generates the possible random values that follow the data distribution. These new numbers are used in some simulation process.

The probability density of the original and simulated data can be compared, see Figure 9.

```
> data(soil)
> # set.seed(9473)
> simulated <- montecarlo(soil$pH,1000)
> h<-graph.freq(simulated,nclass=7,plot=FALSE)

> par(mar=c(2,0,2,1),cex=0.6)
> plot(density(soil$pH),axes=F,main="pH density of the soil\ncon Ralstonia",xlab="",lwd=4)
```

- > axis(1,0:12)
- > legend("topright",c("Original","Simulated"),lty=c(1,4),col=c("black", "blue"), lwd=4)

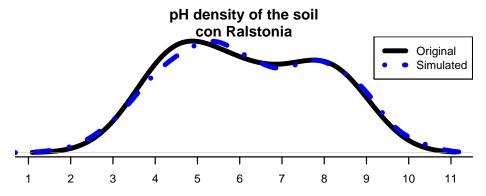

Figure 9: Distribution of the simulated and the original data

1000 data was simulated, being the frequency table:

#### > round(table.freq(h),2)

	Lower	Upper	Main	Frequency	Percentage	CF	CPF
1	1.50	2.81	2.16	20	2.0	20	2.0
2	2.81	4.12	3.47	120	12.0	140	14.0
3	4.12	5.43	4.78	238	23.8	378	37.8
4	5.43	6.74	6.09	225	22.5	603	60.3
5	6.74	8.05	7.40	198	19.8	801	80.1
6	8.05	9.36	8.70	168	16.8	969	96.9
7	9.36	10.67	10.02	31	3.1	1000	100.0

> lines(density(simulated), col="blue", lty=4,lwd=4)

Some statistics, original data:

> summary(soil\$pH)

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 3.800 4.700 6.100 6.154 7.600 8.400
```

#### Some statistics, montecarlo simulate data:

```
> summary(simulated)
```

```
Min. 1st Qu. Median Mean 3rd Qu. Max. 1.600 4.776 6.090 6.218 7.737 10.660
```

## 8.3 Re-Sampling in linear model

It uses the permutation method for the calculation of the probabilities of the sources of variation of ANOVA according to the linear regression model or the design used. The principle is that the Y response does not depend on the averages proposed in the model; hence, the Y values can be permutated and many model estimates can be constructed. On the basis of the patterns of the random variables of the elements under study, the probability is calculated in order to measure the significance.

For a variance analysis, the data should be prepared similarly. The function to use is: resampling.model()

```
> data(potato)
> potato[,1]<-as.factor(potato[,1])</pre>
> potato[,2]<-as.factor(potato[,2])</pre>
> model<-"cutting~variety + date + variety:date"
> analysis <- resampling.model(model, potato, k=100)
> Xsol<-as.matrix(round(analysis$solution,2))</pre>
> print(Xsol,na.print = "")
              Df Sum Sq Mean Sq F value Pr(>F) Resampling

               2
                  13.89
                            6.95
                                    2.01
                                            0.18
                                                        0.16
variety:date
              2
                   4.85
                            2.43
                                     0.70
                                            0.51
                                                        0.61
Residuals
              12
                  41.48
                            3.46
```

The function resampling.model() can be used when the errors have a different distribution from normal

### 8.4 Simulation in linear model

Under the normality assumption

Under the assumption of normality, the function generates pseudo experimental errors under the proposed model, and determines the proportion of valid results according to the analysis of variance found.

The function is: simulation.model(). The data are prepared in a table, similarly to an analysis of variance.

Considering the example proposed in the previous procedure:

```
> simModel <- simulation.model(model, potato, k=100,console=TRUE)
Simulation of experiments</pre>
```

\_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ \_ Proposed model: cutting variety + date + variety:date Analysis of Variance Table Response: cutting Df Sum Sq Mean Sq F value Pr(>F) 1 25.087 25.0868 7.2580 0.01952 \* date 2 13.892 6.9459 2.0096 0.17671 variety:date 2 4.853 2.4265 0.7020 0.51484 12 41.477 3.4564 Residuals Signif. codes: 0 Ś\*\*\*Š 0.001 Ś\*\*Š 0.01 Ś\*Š 0.05 Ś.Š 0.1 Ś Š 1 Validation of the analysis of variancia for the proposed model Simulations: 100 F value % Acceptance % Rejection variety 1 7.2580377 49 2 2.0095604 60 40 variety:date 2 0.7020312 61 39 Criterion variety nonacceptable date acceptable acceptable variety:date

The validation is referred to the percentage of decision results equal to the result of the ANOVA decision. Thus, 61% of the results simulated on the interaction variety\*date gave the same result of acceptance or rejection obtained in the ANOVA.

### 8.5 Path Analysis

It corresponds to the "path analysis" method. The data correspond to correlation matrices of the independent ones with the dependent matrix (XY) and between the independent ones (XX).

It is necessary to assign names to the rows and columns in order to identify the direct and indirect effects.

```
> corr.x<- matrix(c(1,0.5,0.5,1),c(2,2))
> corr.y<- rbind(0.6,0.7)
> names<-c("X1","X2")
> dimnames(corr.x)<-list(names,names)
> dimnames(corr.y)<-list(names,"Y")
> output<-path.analysis(corr.x,corr.y)</pre>
```

Direct(Diagonal) and indirect effect path coefficients

X1 X2 X1 0.3333333 0.2666667 X2 0.1666667 0.5333333

### 8.6 Line X Tester

It corresponds to a crossbreeding analysis of a genetic design. The data should be organized in a table. Only four columns are required: repetition, females, males, and response. In case it corresponds to progenitors, the females or males field will only be filled with the corresponding one. See the heterosis data. Reference [16].

Example with the heterosis data, locality 2.

```
Replication
                   Female
                             Male
109
               1
                     LT-8 TS-15 2.65
               1
                     LT-8 TPS-13 2.26
110
               1 Achirana TPS-13 3.55
131
               1 Achirana TPS-67 3.05
132
140
               1 Achirana
                             <NA> 3.35
. . .
              3
                     <NA> TPS-67 2.91
215
```

where  $\langle NA \rangle$  is empty.

If it is a progeny, it comes from a "Female" and a "Male." If it is a progenitor, it will only be "Female" or "Male."

The following example corresponds to data of the locality 2:

24 progenies 8 females 3 males 3 repetitions

They are 35 treatments (24, 8, 3) applied to three blocks.

```
> rm(list=ls())
> data(heterosis)
> site2<-subset(heterosis,heterosis[,1]==2)
> site2<-subset(site2[,c(2,5,6,8)],site2[,4]!="Control")
> attach(site2)
> output1<-lineXtester(Replication, Female, Male, v2)</pre>
```

## 8.7 Soil Uniformity

The Smith index is an indicator of the uniformity, used to determine the parcel size for research purposes. The data correspond to a matrix or table that contains the response per basic unit, a number of n rows x m columns, and a total of n\*m basic units.

For the test, we will use the rice file. The graphic is a result with the adjustment of a model for the plot size and the coefficient of variation, see Figure 10.

```
> par(mar=c(3,3,4,0),cex=0.7)
> data(rice)
> table<-index.smith(rice,pch=19, col="blue",
+ main="Interaction between the CV and the plot size",type="l",xlab="Size")</pre>
```

## Interaction between the CV and the plot size

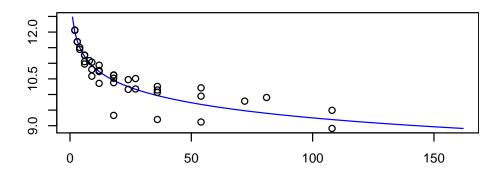

Figure 10: Adjustment curve for the optimal size of plot

- > uniformity <- data.frame(table\$uniformity)
  > bask(uniformity)
- > head(uniformity)

	Size	Width	Length	plots	Vx	CV
1	1	1	1	648	9044.539	13.0
2	2	1	2	324	7816.068	12.1
3	2	2	1	324	7831.232	12.1
4	3	1	3	216	7347.975	11.7
5	3	3	1	216	7355.216	11.7
6	4	1	4	162	7047.717	11.4

## 8.8 Confidence Limits In Biodiversity Indices

The biodiversity indices are widely used for measuring the presence of living things in an ecological area. Many programs indicate their value. The function of 'agricolae' is also to show the confidence intervals, which can be used for a statistical comparison. Use the bootstrap procedure. The data are organized in a table; the species are placed in a column; and in another one, the number of individuals. The indices that can be calculated with the function index.bio() of 'agricolae' are: "Margalef", "Simpson.Dom", "Simpson.Div", "Berger.Parker", "McIntosh", and "Shannon."

In the example below, we will use the data obtained in the locality of Paracsho, district of Huasahuasi, province of Tarma in the department of Junin.

The evaluation was carried out in the parcels on 17 November 2005, without insecticide application. The counted specimens were the following:

> data(paracsho)
> species <- paracsho[79:87,4:6]
> species

	Orden	Family	Number.of.specimens
79	DIPTERA	TIPULIDAE	3
80	LEPIDOPTERA	NOCTUIDAE	1
81	NOCTUIDAE	PYRALIDAE	3
82	HEMIPTERA	ANTHOCORIDAE	1
83	DIPTERA	TACHINIDAE	16
84	DIPTERA	ANTHOCORIDAE	3
85	DIPTERA	${\tt SCATOPHAGIDAE}$	5
86	DIPTERA	SYRPHIDAE	1
87	DIPTERA	MUSCIDAE	3

#### The Shannon index is:

```
> output <- index.bio(species[,3],method="Shannon",level=95,nboot=200)
Method: Shannon
The index: 3.52304
95 percent confidence interval:
3.180131; 4.260501</pre>
```

### 8.9 Correlation

The function correlation() of 'agricolae' makes the correlations through the methods of Pearson, Spearman and Kendall for vectors and/or matrices. If they are two vectors, the test is carried out for one or two lines; if it is a matrix one, it determines the probabilities for a difference, whether it is greater or smaller.

For its application, consider the soil data: data(soil)

```
> data(soil)
> correlation(soil[,2:4],method="pearson")
```

```

## 8.10 tapply.stat()

Gets a functional calculation of variables grouped by study factors.

Application with 'agricolae' data: max(yield)-min(yield) by farmer

```
> data(RioChillon)
> attach(RioChillon$babies)
> tapply.stat(yield,farmer,function(x) max(x)-min(x))
```

```
farmer yield
1
   AugustoZambrano
                     7.5
2
         Caballero 13.4
3
        ChocasAlto 14.1
4
        FelixAndia 19.4
5
       Huarangal-1
                     9.8
6
       Huarangal-2
                     9.1
7
       Huarangal-3
                     9.4
          Huatocay 19.4
9 IgnacioPolinario 13.1
```

#### > detach(RioChillon\$babies)

It corresponds to the range of variation in the farmers' yield.

The function "tapply" can be used directly or with function.

If A is a table with columns 1,2 and 3 as category, and 5,6 and 7 as variables, then the following procedures are valid:

```
tapply.stat(A[,5:7], A[,1:3],mean)
tapply.stat(A[,5:7], A[,1:3],function(x) mean(x,na.rm=TRUE))
tapply.stat(A[,c(7,6)], A[,1:2],function(x) sd(x)*100/mean(x))
```

## 8.11 Coefficient of variation of an experiment

If "model" is the object resulting from an analysis of variance of the function aov() or lm() of R, then the function cv.model() calculates the coefficient of variation.

```
> data(sweetpotato)
> model <- model<-aov(yield ~ virus, data=sweetpotato)
> cv.model(model)
[1] 17.1666
```

## 8.12 Skewness and kurtosis

The skewness and kurtosis results, obtained by 'agricolae', are equal to the ones obtained by SAS, MiniTab, SPSS, InfoStat, and Excel.

If x represents a data set:

```
> x<-c(3,4,5,2,3,4,5,6,4,NA,7)
skewness is calculated with:
> skewness(x)
[1] 0.3595431
and kurtosis with:
> kurtosis(x)
[1] -0.1517996
```

### 8.13 Tabular value of Waller-Duncan

The function Waller determines the tabular value of Waller-Duncan. For the calculation, value F is necessary, calculated from the analysis of variance of the study factor, with its freedom degrees and the estimate of the variance of the experimental error. Value K, parameter of the function is the ratio between the two types of errors (I and II). To use it, a value associated with the alpha level is assigned. When the alpha level is 0.10, 50 is assigned to K; for 0.05, K=100; and for 0.01, K=500. K can take any value.

```
> q<-5
> f<-15
> K<-seq(10,1000,100)
> n<-length(K)
> y<-rep(0,3*n)
> dim(y)<-c(n,3)
> for(i in 1:n) y[i,1]<-waller(K[i],q,f,Fc=2)
> for(i in 1:n) y[i,2]<-waller(K[i],q,f,Fc=4)
> for(i in 1:n) y[i,3]<-waller(K[i],q,f,Fc=8)</pre>
```

Function of Waller to different value of parameters K and Fc The next procedure illustrates the function for different values of K with freedom degrees of 5 for the numerator and 15 for the denominator, and values of calculated F, equal to 2, 4, and 8.

```
> par(mar=c(3,3,4,0),cex=0.7)
> plot(K,y[,1],type="l",col="blue",ylab="waller",bty="l")
> lines(K,y[,2],type="l",col="brown",lty=2,lwd=2)
> lines(K,y[,3],type="l",col="green",lty=4,lwd=2)
> legend("topleft",c("2","4","8"),col=c("blue","brown","green"),lty=c(1,8,20),
+ lwd=2,title="Fc")
> title(main="Waller in function of K")
```

## Generating table Waller-Duncan

```
> K<-100
> Fc<-1.2
> q<-c(seq(6,20,1),30,40,100)
```

```
> f < -c(seq(4,20,2),24,30)
> n<-length(q)
> m<-length(f)
> W.D < -rep(0,n*m)
> dim(W.D) < -c(n,m)
> for (i in 1:n) {
+ for (j in 1:m) {
+ W.D[i,j]<-waller(K, q[i], f[j], Fc)
> W.D<-round(W.D,2)
> dimnames(W.D)<-list(q,f)</pre>
> cat("table: Waller Duncan k=100, F=1.2")
table: Waller Duncan k=100, F=1.2
> print(W.D)
                8

```

#### 8.14 AUDPC

The area under the disease progress curve (AUDPC), see Figure 10 calculates the absolute and relative progress of the disease. It is required to measure the disease in percentage terms during several dates, preferably equidistantly.

```
> days<-c(7,14,21,28,35,42)
> evaluation<-data.frame(E1=10,E2=40,E3=50,E4=70,E5=80,E6=90)
> print(evaluation)

E1 E2 E3 E4 E5 E6
1 10 40 50 70 80 90
```

```
> absolute1 <-audpc(evaluation,days)
> relative1 <-round(audpc(evaluation,days,"relative"),2)</pre>
```

#### 8.15 AUDPS

The Area Under the Disease Progress Stairs (AUDPS), see Figure 11. A better estimate of disease progress is the area under the disease progress stairs (AUDPS). The AUDPS approach improves the estimation of disease progress by giving a weight closer to optimal to the first and last observations...

```
> absolute2 <-audps(evaluation,days)
> relative2 <-round(audps(evaluation,days,"relative"),2)</pre>
```

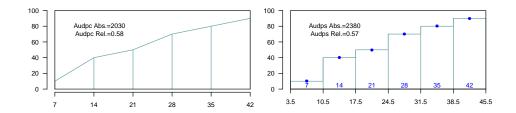

Figure 11: Area under the curve (AUDPC) and Area under the Stairs (AUDPS)

## 8.16 Non-Additivity

Tukey's test for non-additivity is used when there are doubts about the additivity veracity of a model. This test confirms such assumption and it is expected to accept the null hypothesis of the non-additive effect of the model.

For this test, all the experimental data used in the estimation of the linear additive model are required. Use the function nonadditivity() of 'agricolae'. For its demonstration, the experimental data "potato", of the package 'agricolae', will be used. In this case, the model corresponds to the randomized complete

```
> data(potato)
> potato[,1]<-as.factor(potato[,1])
> model<-lm(cutting ~ date + variety,potato)
> df<-df.residual(model)
> MSerror<-deviance(model)/df
> attach(potato)
> analysis<-nonadditivity(cutting, date, variety, df, MSerror)
Tukey's test of nonadditivity
cutting</pre>
```

block design, where the treatments are the varieties.

P: 15.37166 Q: 77.44441

```
Analysis of Variance Table

Response: residual

Df Sum Sq Mean Sq F value Pr(>F)

Nonadditivity 1 3.051 3.0511 0.922 0.3532

Residuals 14 46.330 3.3093

> detach(potato)
```

According to the results, the model is additive because the p.value 0.35 is greater than 0.05.

### 8.17 LATEBLIGHT

LATEBLIGHT is a mathematical model that simulates the effect of weather, host growth and resistance, and fungicide use on asexual development and growth of Phytophthora infestans on potato foliage, see Figure 12

LATEBLIGHT Version LB2004 was created in October 2004 (Andrade-Piedra et al., 2005a, b and c), based on the C-version written by B.E. Ticknor ('BET 21191 modification of cbm8d29.c'), reported by Doster et al. (1990) and described in detail by Fry et al. (1991) (This version is referred as LB1990 by Andrade-Piedra et al. [2005a]). The first version of LATEBLIGHT was developed by Bruhn and Fry (1981) and described in detail by Bruhn et al. (1980).

```
> f <- system.file("external/weather.csv", package="agricolae")</pre>
> weather <- read.csv(f,header=FALSE)
> f <- system.file("external/severity.csv", package="agricolae")</pre>
> severity <- read.csv(f)
> weather[,1]<-as.Date(weather[,1],format = "%m/%d/%Y")</pre>
> # Parameters dates
> dates<-c("2000-03-25","2000-04-09","2000-04-12","2000-04-16","2000-04-22")
> dates <- as. Date (dates)
> EmergDate <- as.Date("2000/01/19")</pre>
