PREFACE

R is a functional programming system exclusive to manage data in statistics and related sciences, such as mathematics, in environments like Windows, Linux and MAC. 'Agricolae' is a package of functions for R applied to agricultural research.

The package 'agricolae' offers a broad functionality in the design of experiments, especially for experiments in agriculture and improvements of plants, which can also be used for other purposes. It contains the following designs: lattice, alpha, cyclic, balanced incomplete block designs, complete randomized blocks, Latin, Graeco-Latin, augmented block designs, divided parcels, divided blocks. It also has several procedures of experimental data analysis, such as the comparisons of treatments of Waller-Duncan, Bonferroni, Duncan, Student-Newman-Keuls, Scheffe, or the classic LSD and Tukey; and non-parametric comparisons, such as Kruskal-Wallis, Friedman, Durbin and Waerden, stability analysis, and other procedures applied in genetics, as well as procedures in biodiversity and descriptive statistics.

For more details on the use of 'agricolae', see the reference manual and the aid system in HTML, which can be found in the menu of R.

1 INSTALLATION OF AGRICOLAE AND USE IN R

1.1 INSTALLATION

The main program of R should be already installed in the platform of your computer (Windows, Linux or MAC). If it is not installed yet, you can download it from the R project (www.r-project.org) of a repository CRAN (R Development Core Team, 2012). As it is a free program, no identification is required. The packages can be incorporated through an installation process, directly from the platform of R.

'Agricolae' is a package for R, and as such its installation is just like any other package of R.

For Windows, the R program (version 2.15.1 or higher) is required.

If the R program is already installed in Windows or in another platform, the installation of 'agricolae' can be done directly from the console of R through Internet, that is

install.packages("agricolae)

A repository should be selected and the system is installed automatically.

If there is no Internet connection, it is necessary to copy the file agricolae_1.1-2. zip for Windows from the page of the R project.

The file agricolae_1.1-2.zip (De Mendiburu, 2012) can be downloaded from the R repository in the following addresses: www.r-project.org or http://cran.at.r-project.org/web/packages/agricolae/index.html

The file can be directly incorporated into R installing from the console with the following instruction set if the file is located in the address E: install.packages("E:/agricolae 1.1-2.zip)

It can also be installed from the R menu:

Packages, Install package(s) from local zip files.... Selecting the file zip does not require any unpacking.

For a complete functionality, 'agricolae' requires other packages.

MASS: for the generalized inverse used in the function PBIB.test() klaR: for the function triplot() used in the function AMMI() akima: for the use of the function interpp() used in grid3p() for interpolation Cluster: for the use of the function consensus()

1.2 USE IN R

Since 'agricolae' is a package of functions, these are operational when they are called directly from the console of R and are integrated to all the base functions of R.

The following orders are frequent: Load the package to the memory: library(agricolae) Download: detach(package:agricolae)

Once the package is loaded, you can:

List the database: data(package="agricolae") Load the sweet potato data: data(sweetpotato)

See its structure: str(sweetpotato)
Publish its content: fix(sweetpotato)

In order to continue with the command line, do not forget to close the open windows with any R order.

For help: help(sweetpotato); ? sweetpotato To search any functions: apropos("design")

[1] "design.ab""design.alpha""design.bib""design.crd"[5] "design.cyclic""design.dau""design.graeco""design.lattice"[9] "design.lsd""design.rcbd""design.split""design.strip"

For the use of symbols that do not appear in the keyboard in Spanish, such as: \sim , [,], &, $^{\wedge}$, |. <, >, {, }, $^{\otimes}$ or others, use the table 6.10.

2 DESCRIPTIVE STATISTICS

The package 'agricolae' provides some complementary functions to the R program, specifically for the management of the histogram.

2.1 HISTOGRAM

The histogram is constructed with the function graph.freq() and is associated to other functions: polygon.freq, table.freq, stat.freq, intervals.freq, sturges.freq, join.freq, ojiva.freq, and normal.freq.

Example 1.1 Data generated in R. (students' weight). Figure 2.1

```
c( 68, 53, 69.5, 55, 71, 63, 76.5, 65.5, 69, 75, 76, 57, 70.5, 71.5, 56, 81.5, 69, 59, 67.5, 61, 68, 59.5, 56.5, 73, 61, 72.5, 71.5, 59.5, 74.5, 63) \rightarrow weight
```

Load the package 'agricolae':

```
library(agricolae)
par(mfrow=c(2,2),cex=0.7)
h1<- graph.freq(weight, col="yellow", frequency =1, main="Absolute</pre>
frequency", axes=FALSE)
axis(1,h1$breaks)
axis(2,0:10)
h2<- graph.freq(weight, frequency =2, main=" polygon of frequency",
axes=FALSE)
axis(1,h2$breaks)
axis(2, seq(0, 0.3, 0.1))
polygon.freq(h2, col="blue", lwd=2, frequency =2)
h3<- graph.freg(weight, col="brown", frequency =3, main="density",
axes=FALSE)
axis(1,h2$breaks)
h4<- graph.freq(weight, col="blue", frequency =3, main=" normal
density", density=4, axes=FALSE)
axis(1,h2$breaks)
normal.freq(h4, col="red", lty=4,lwd=2, frequency=3)
```

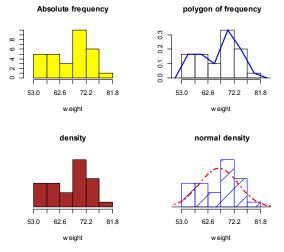

Figure 2.1 Histograms, polygon and density

2.2 HANDLING SCALES

It refers to the scale changes in the axes. Figure 2.2

```
par(mfrow=c(2,2),cex=0.7)
h5<- graph.freq(weight, axes=FALSE, frequency =1, main="Absolute
frequency")
axis(1,h5\$breaks,las=2)
axis(2, h5$count)
h6<- graph.freg(weight, axes=FALSE, nclass=5, main="frecuency with 5
classes")
axis(1,h6$breaks,las=2)
axis(2, seq(0, 10))
normal.freq(h6,col="red")
h7<- graph.freq(weight, density=6, col="blue", frequency =3,
main="density", axes=FALSE)
lines(density(weight),col="brown",lwd=2)
axis(1,h7$breaks,las=2)
h8<- graph.freq(weight, border=0, frequency =3, main="polygon and
density", axes=FALSE)
polygon.freq(h8,col="blue", frequency =3)
lines(density(weight),col="brown",lwd=2)
axis(1,h7$breaks,las=2)
          Absolute frequency
                                        frecuency with 5 classes
                                    10
   10
                                    ω
                                    9
   2
                                    4
                                    2
              62.6
           57.8
                 67.4
                    72.2
                      77.0
                                            58.8
                                                64.6
                                                      76.2
                                                   70.4
               w eight
                                                w eight
               density
                                          polygon and density
```

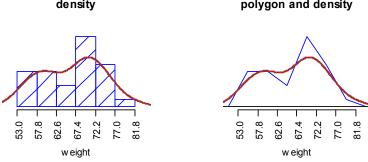

Figure 2.2. Scale change of the axes of coordinates

```
h9<-ojiva.freq(h5,axes=FALSE,type="b", main="ojiva of h5", col="red")
axis(2,round(h9[,2],1),las=2)
axis(1,round(h9[,1],1),las=2)
```

2.3 FREQUENCY TABLES AND STATISTICS

```
Rounded off to two decimals:
                                           stat.freq(h6)
                                           $variance
                                           [1] 50.42133
round(table.freq(h6), 2)
                                           $mean
                                           [1] 66.72667
  Lower Upper Main freq relative CF RCF
                                           $median
   53.0 58.8 55.9 5
                           0.17 5 0.17
   58.8 64.6 61.7
                                           [1] 67.08571
                      7
                           0.23 12 0.40
                                           $mode
                     7
   64.6 70.4 67.5
                           0.23 19 0.63
                                                   - ]
                                           [ -
                                                            mode
   70.4
        76.2 73.3
                      9
                            0.30 28 0.93
                                            70.4 76.2
                                                         71.68889
   76.2 82.0 79.1
                      2
                           0.07 30 1.00
```

2.4 REPRODUCING HISTOGRAMS AND USE OF hist()

The class of graph.freq() is graph.freq. Figure 2.3

Reproducing the histogram h6 (5 classes)

```
h10<-plot(h6, axes=FALSE, main="frequency with 5 classes")
axis(1,h6$breaks,las=2)
axis(2,seq(0,10))
normal.freq(h6,col="red")
round(summary(h6),2)

Lower Upper Main freq relative CF RCF
53.0 58.8 55.9 5 0.17 5 0.17
58.8 64.6 61.7 7 0.23 12 0.40
64.6 70.4 67.5 7 0.23 19 0.63
70.4 76.2 73.3 9 0.30 28 0.93
76.2 82.0 79.1 2 0.07 30 1.00
```

The class types of the functions hist() and graph.freq() are 'histogram' and 'graph.freq', respectively. However, it is possible to establish compatibility between both functions.

```
hh <- hist(weight,nclass=5, plot=FALSE) # Reports 7 classes
# hist(weight,nclass=4) # Reports 4 classes</pre>
```

In order to show the relative frequencies, you can use graph.freq() with the object hh created by hist(), without modifying the classes.

```
h11<-graph.freq(hh, frequency=2,
col=colors()[367],main="relative",axes=F)
axis(1,h11$breaks,las=2)
axis(2,round(h11$relative,2),las=2)</pre>
```

See the summaries: > summary(hh), summary(h11)

The functions of 'agricolae' for the management of histograms function correctly on the objects created by the function hist() of R.

2.5 HISTOGRAM BASED ON GROUPED DATA

If there are grouped data, you can graphic and obtain the histogram summaries with the function graph.freq(), as, for example, in the following table:

```
10-20 20-30 30-40 40-50
              15
                    18
In R we have:
classes <-c(0, 10, 20, 30, 40, 50)
frec <- c(3, 8, 15, 18, 6)
h12 <- graph.freq(classes, counts=frec, xlab="Classes",</pre>
main="Classes")
summary(h12)
  Lower Upper Main freq relative CF RCF
                5
                       3
           10
                              0.06 3 0.06
     10
           20
                 15
                       8
                              0.16 11 0.22
     20
           30
                 25
                      15
                              0.30 26 0.52
     30
           40
                 35
                      18
                              0.36 44 0.88
           50
                 45
                              0.12 50 1.00
     40
                       6
```

All the functions of 'agricolae' can be applied, including plot().

```
plot(h11, frequency=2, col=colors()[367],main="relative",axes=F)
axis(1,h11$breaks,las=2)
axis(2,round(h11$relative,2),las=2)
plot(h12, xlab="Classes", main="Classes")
```

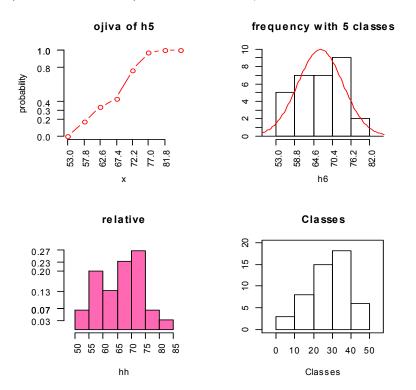

Figure 2.3 New scales for the histograms

2.6 JOINING CLASSES

Knowing the students' weight, the original intervals can be changed, joining, for example:

```
nuevas<- join.freq(h5$breaks,1:2)</pre>
intervals.freq(h5$breaks)
    lower upper
                         intervals.freq(nuevas)
[1,] 53.2 58.0
                             lower upper
[2,] 58.0 62.8
                         [1,] 53.2 62.8
[3,] 62.8 67.6
                         [2,] 62.8 67.6
    67.6 72.4
                         [3,] 67.6 72.4
[4,]
[5,] 72.4 77.2
                         [4,] 72.4 77.2
[6,] 77.2 82.0
                         [5,] 77.2 82.0
                         h13 <- graph.freq(peso, breaks=nuevas)</pre>
```

3 EXPERIMENT DESIGNS

The package 'agricolae' presents special functions for the creation of the field book for experimental designs. Due to the random generation, this package is quite used in agricultural research.

For this generation, certain parameters are required, as for example the name of each treatment, the number of repetitions, and others, according to the design (Cochran, 1992; Kuehl, 2000; Montgomery, 2002; LeClerg, 1962). There are other parameters of random generation, as the seed to reproduce the same random generation or the generation method (See the reference manual of agriculture http://cran.at.r-project.org/web/packages/agricolae/agricolae.pdf)

3.1 COMPLETELY RANDOMIZED DESIGNS

They only require the names of the treatments and the number of their repetitions.

```
trt <- c("A", "B", "C")
repetition \leftarrow c(4, 3, 4)
plan1 <- design.crd(trt,r=repetition)</pre>
  plots trt r
1
     1 A 1
2
      2
         C 1
3
      3 A 2
4
      4 A 3
5
      5 B 1
6
      6 C 2
      7 C 3
7
8
      8 B 2
9
      9 A 4
10
     10 B 3
11
     11 C 4
```

Excel:

```
write.csv(plan1, "plan1.csv", row.names=FALSE)
```

3.2 RANDOMIZED COMPLETE BLOCK DESIGN

They require the names of the treatments and the number of blocks.

The plan can be sent to excel as a field book.

3.3 LATIN SQUARE DESIGNS

They require the names of the treatments.

```
trt <- c("A", "B", "C", "D")
plan3 <- design.lsd(trt, seed=55, number=101, first=FALSE)
t(matrix(plan3[,4],c(4,4)))
        [,1] [,2] [,3] [,4]
[1,] "A" "B" "D" "C"
[2,] "B" "C" "A" "D"
[3,] "D" "A" "C" "B"
[4,] "C" "D" "B" "A"</pre>
```

3.4 GRAECO-LATIN DESIGNS

They require the names of the treatments of each factor of study.

```
T1 <- c("A", "B", "C", "D")
T2 <- 1:4
plan4 <- design.graeco(T1,T2, seed=55, number=101)
t(matrix(paste(plan4[,4],plan4[,5]),c(4,4)))

[,1] [,2] [,3] [,4]
[1,] "A 3" "D 4" "C 1" "B 2"
[2,] "D 1" "A 2" "B 3" "C 4"
[3,] "C 2" "B 1" "A 4" "D 3"
[4,] "B 4" "C 3" "D 2" "A 1"
```

3.5 BALANCED INCOMPLETE BLOCK DESIGNS

They require the names of the treatments and the size of the block.

According to the produced information, they are five blocks of size 4, being the matrix:

```
t(matrix(plan5[,3],c(4,5)))
   [,1] [,2] [,3]
                             [,4]
            "Control" "C"
[1,] "B"
                             "A"
[2,] "D"
            "A" "C"
                             "B"
[3,] "B"
           "C"
                    "Control" "D"
[4,] "C"
           "D"
                   "A" "Control"
                    "D"
[5,] "Control" "B"
                             "A"
```

It can be observed that the treatments have four repetitions. The parameter lambda has three repetitions, which means that a couple of treatments are together on three occasions. For example, B and E are found in the blocks I, III and V.

3.6 CYCLIC DESIGNS

They require the names of the treatments, the size of the block and the number of repetitions. This design is used for 6 to 30 treatments. The repetitions are a multiple of the size of the block; if they are six treatments and the size is 3, then the repetitions can be 6, 9, 12, etc.

```
trt <- c("A", "B", "C", "D", "E", "F")
plan5 <- design.cyclic(trt,k=3, r=6, seed=55, number=101)</pre>

```

12 blocks of 4 treatments each have been generated.

3.7 LATTICE DESIGNS

They require a number of treatments of a perfect square; for example 9, 16, 25, 36, 49, etc.

They can generate a simple lattice (2 rep.) or a triple lattice (3 rep.)

generating a triple lattice design for 9 treatments 3x3

```
plan6 <- design.lattice(k=3, seed=55, number=101)</pre>
print(plan6)

3.8 ALPHA DESIGNS

These designs are generated by the alpha arrangements (Patterson & Williams, 1976). They are similar to the lattice designs, but the tables are rectangular, with s blocks x k treatments. The number of treatments should be equal to s*k and all the experimental units, r*s*k.

```
Genotype<-paste("geno", 1:15, sep = "")
plan7 <- design.alpha(Genotype, k=3, r=2, seed=55)</pre>
```

[5,] "geno10" "geno2" "geno9"
```

3.9 AUGMENTED BLOCK DESIGNS

These are designs for two types of treatments: the control treatments (common) and the increased treatments. The common treatments are applied in complete randomized blocks, and the increased treatments, at random. Each treatment should be applied in any block once only. It is understood that the common treatments are of a greater interest; the standard error of the difference is much smaller than when between two increased ones in different blocks. The function design.dau() achieves this purpose.

```
common <- c("A", "B", "C", "D")
others <- c("t", "u", "v", "w", "x", "y", "z")
plan8 <- design.dau(common, others, r=5, seed=55, number=101)
by(plan8$trt, plan8$block, function(x) as.character(x))
block: 1

                 D
32
     132
             5
```

For augmented randomized complete block designs, use the function design.crd().

3.10 SPLIT-PLOT DESIGNS

These designs have two factors, one is applied in plots and is defined as A in a randomized complete block design; and a second factor, which is applied in the subplots of each plot applied at random. The function design.split() permits to find the experimental plan for this design.

```
t1<-c("A", "B", "C", "D")
t2<-c("a", "b", "c")
plan9 <-design.split(t1,t2,r=3,number=101,seed=45, first=FALSE)</pre>
print(plan9)
  plots block t1 t2
    101 1 A b
2
           1 A a
    101
3
    101
           1 A c
4
    102
           1 B c
   112
           3 D c
p<-plan9$t1[seq(1,36,3)]</pre>
q<-NULL
for(i in 1:12) q < -c(q,paste(plan9$t2[3*(i-1)+1],plan9$t2[3*(i-1)+1]]
1)+2],plan9$t2[3*(i-1)+3])
In the plots
> print(t(matrix(p,c(4,3))))
     [,1] [,2] [,3] [,4]
[1,] "A" "B" "C" "D"
[2,] "B"
         "D" "C"
                    "A"
[3,] "A" "B" "C" "D"
> print(t(matrix(q,c(4,3))))
     [,1] [,2]
                   [,3]

[2,] "acb" "acb" "bac" "bac"
[3,] "c b a" "c a b" "a c b" "a b c"
```

3.11 STRIP-PLOT DESIGNS

These designs are used when there are two types of treatments (factors) and are applied separately in large plots, called bands, in a vertical and horizontal direction of the block, obtaining the divided blocks. Each block constitutes a repetition.

```
t1<-c("A", "B", "C")
t2<-c("a", "b", "c", "d")
```

```
plan10 <-design.strip(t1,t2,r=3,number=101,seed=45)</pre>
print(plan10)
  plots block t1 t2
1
    101 1 B b

t3<-paste(plan10$t1,plan10$t2)
B1 < -t (matrix (t3[1:12], c(4,3)))
B2 < -t (matrix (t3[13:24], c(4,3)))
B3 < -t (matrix (t3[25:36], c(4,3)))
> print(B1)
    [,1] [,2] [,3] [,4]
[1,] "B b" "B a" "B d" "B c"
[2,] "C b" "C a" "C d" "C c"
[3,] "A b" "A a" "A d" "A c"
> print(B2)
    [,1] [,2] [,3] [,4]
[1,] "A c" "A a" "A d" "A b"
[2,] "C c" "C a" "C d" "C b"
[3,] "B c" "B a" "B d" "B b"
> print(B3)
     [,1] [,2] [,3] [,4]
[1,] "B d" "B a" "B b" "B c"
[2,] "C d" "C a" "C b" "C c"
[3,] "A d" "A a" "A b" "A c"
```

4 MULTIPLE COMPARISONS

For the analyses, the following functions of 'agricolae' are used: LSD.test(), HSD.test(), duncan.test(), scheffe.test, waller.test, SNK.test() (Steel, 1996) and durbin.test(), kruskal(), friedman() and waerden.test (Conover, 1999).

For every statistical analysis, the data should be organized in columns. For the demonstration, the 'agricolae' database will be used.

The 'sweetpotato' data correspond to a completely random experiment in field with plots of 50 sweet potato plants, subjected to the virus effect and to a control without virus (See the reference manual of the package).

```
data(sweetpotato)
model<-aov(yield~virus, data=sweetpotato)

cv.model(model)
[1] 17.16660
attach(sweetpotato)
mean(yield)
[1] 27,625</pre>
```

Model parameters: Degrees of freedom and variance of the error:

```
df<-df.residual(model)
MSerror<-deviance(model)/df</pre>
```

4.1 THE LEAST SIGNIFICANT DIFFERENCE (LSD)

It includes the multiple comparison through the method of the minimum significant difference (Least Significant Difference), (Steel, 1997).

```
# comparison <- LSD.test(yield, virus, df, MSerror)</pre>
LSD.test(model, "virus")
Study:

а
                24.4
b
        CC
                12.87
```

In the function LSD.test(), the multiple comparison was carried out. In order to obtain the probabilities of the comparisons, it should be indicated that groups are not required; thus:

```
alpha: 0.05; Df Error: 8
Critical Value of t: 2.306004

Comparison between treatments means

Difference pvalue sig LCL UCL
cc - fc 11.5333333 0.0176377595 * 2.604368 20.462299
cc - ff -11.9333333 0.0150730851 * -20.862299 -3.004368
cc - oo -12.5000000 0.0120884239 * -21.428965 -3.571035
fc - ff -23.4666667 0.0003023690 *** -32.395632 -14.537701
fc - oo -24.0333333 0.0002574929 *** -32.962299 -15.104368
ff - oo -0.5666667 0.8872673216 -9.495632 8.362299
```

The significance code "sig" is interpreted as:

```
"***": p.valor < 0.001

"** ": 0.001 <p.valor < 0.01

"* ": 0.01 < p.valor < 0.05

". ": 0.05 < p.valor < 0.10
```

4.2 BONFERRONI

With the function LSD.test() we can make adjustments to the probabilities found, as for example the adjustment by Bonferroni.

```
LSD.test(model, "virus", group=F, p.adj= "bon")

LSD t Test for yield
P value adjustment method: bonferroni

alpha: 0.05; Df Error: 8
Critical Value of t: 3.478879

Comparison between treatments means

ff - oo -0.56666667 1.000000 -14.037064 12.9037305
```

Other comparison tests can be applied, such as "duncan", "Student-Newman-Keuls", "tukey", and "waller-duncan."

For "duncan", use the function duncan.test(); for "Student-Newman-Keuls", the function SNK.test(); for "tukey", the function HSD.test(); for "scheffe", the function scheffe.test(); and for "waller-duncan", the function waller.test(). The parameters are the same. "Waller" also requires the value of F-calculated of the ANOVA treatments. If the model is used as a parameter, this is no longer necessary.

4.3 DUNCAN'S NEW MULTIPLE-RANGE TEST

It corresponds to the Duncan's Test (Steel, 1997).

```
duncan.test(model, "virus")

4.6 WALLER-DUNCAN'S BAYESIAN K-RATIO t-TEST

In 1975, Duncan continued the multiple comparison procedures, introducing the criterion of minimizing both experimental errors; for this, he used the Bayes' theorem, obtaining one new test called Waller-Duncan (Steel, 1997).

The value of calculated F is 17,345. For the comparative treatment analysis, it is required that 'sweetpotato' be active, thus:

```
attach(sweetpotato)
then:
waller.test(yield,virus,df,MSerror,Fc= 17.345, group=F)
In another case with only invoking the model object:
comparison2 <- waller.test(model, "virus", group=F)</pre>
Waller-Duncan K-ratio t Test for yield
This test minimizes the Bayes risk under additive
loss and certain other assumptions.
                       100.00000
K ratio
Error Degrees of Freedom 8.00000
Error Mean Square 22.48917
F value
                        17.34478
Critical Value of Waller 2.23600
virus, means
     yield std.err replication
cc 24.40000 2.084067
                              3
fc 12.86667 1.246774
ff 36.33333 4.233727
00 36.90000 2.482606
Minimum Significant Difference 8.657906
Comparison between treatments means
       Difference significant

ff - cc 11.9333333
                         TRUE
oo - cc 12.5000000
                        TRUE
ff - fc 23.4666667
                        TRUE
oo - fc 24.0333333
                        TRUE
```

It is indicated that the virus effect "ff" is not significant to the control "oo."

FALSE

The found object "compara" has information to make other procedures.

oo - ff 0.5666667

4.7 SCHEFFE'S TEST

This method, created by Scheffe in 1959, is very general for all the possible contrasts and their confidence intervals. The confidence intervals for the averages are very broad, resulting in a very conservative test for the comparison between treatment averages (Steel, 1997).

```
# analysis of variance:
model<-aov(yield~virus, data=sweetpotato)</pre>
scheffe.test(model, "virus", group=TRUE,
main="Yield of sweetpotato\nDealt with different virus")
Study: Yield of sweetpotato

4.9 ANALYSIS OF BALANCED INCOMPLETE BLOCKS

This analysis can come from balanced or partially balanced designs. The function BIB.test() is for balanced designs, and PBIB.test(), for partially balanced designs. In the following example, the 'agricolae' data will be used.

```
#Example linear estimation and design of experiments. (Joshi, 1987)
# Profesor de Estadistica, Institute of Social Sciences Agra, India
# 6 variedades de trigo en 10 bloques de 3 parcelas cada una.
block < -gl(10,3)

The found "model" object can be used for the functions bar.group() and bar.err() for the bar graphics, in the same way as previously.

4.10 PARTIALLY BALANCED INCOMPLETE BLOCKS

The function PBIB.test() (Joshi, 1987) can be used for the lattice and alpha designs.

Consider the following case: Construct the alpha design with 30 treatments, 2 repetitions, and a block size equal to 3.

```
library(agricolae)
library (MASS)
library(lme4)
# alpha design
Genotype<-paste("geno",1:30, sep="")</pre>
r<-2
k < -3
plan<-design.alpha(Genotype,k,r,seed=5)</pre>
alpha design (0,1) - Serie I
Parameters Alpha design
treatmeans: 30
Block size : 3
Blocks : 10
Replication: 2
Efficiency factor
(E ) 0.6170213
<<< Book >>>
```

The generated plan is plan\$book.

table<-data.frame(plan\$book, yield)</pre>

Suppose that the corresponding observation to each experimental unit is:

```
yield <-c(5,2,7,6,4,9,7,6,7,9,6,2,1,1,3,2,4,6,7,9,8,7,6,4,3,2,2,1,1,2,1,1,2,4,5,6,7,8,6,5,4,3,1,1,2,5,4,2,7,6,6,5,6,4,5,7,6,5,5,4)
```

The data table is constructed for the analysis. In theory, it is presumed that a design is applied and the experiment is carried out; subsequently, the study variables are observed from each experimental unit.

```
rm(yield, Genotype)
The analysis:
attach(table)
model <- PBIB.test(block, Genotype, replication, yield, k=3,
group=TRUE)
detach(table)
ANALYSIS PBIB: yield</pre>
```

```

The data on the adjusted averages and their standard error can be illustrated (figure 4.2), since the created object is very similar to the objects generated by the multiple comparisons.

```
par(mfrow=c(2,2),cex=0.6)
C1<-bar.err(model$means[1:7, c(1,3,2,4,5)], ylim=c(0,9), col=0,
main="C1", std=F,border=3)
C2<-bar.err(model$means[8:15, c(1,3,2,4,5)], ylim=c(0,9), col=0,
main="C2", std=F, border =4)
C3<-bar.err(model$means[16:22, c(1,3,2,4,5)], ylim=c(0,9), col=0,
main="C3", std=F, border =2)
C4<-bar.err(model$means[23:30, c(1,3,2,4,5)], ylim=c(0,9), col=0,
main="C4", std=F, border =6)</pre>
```

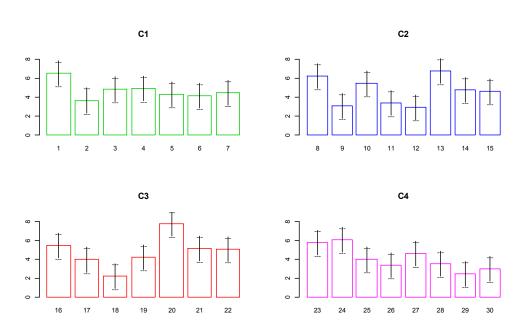

Figure 4.3. Standard deviation in each treatment.

Analysis of balanced lattice 3x3, 9 treatments, 4 repetitions.

Create the data in a text file: latice3x3.txt and read with R:

```

4.12 NON-PARAMETRIC COMPARISONS

The functions for non-parametric multiple comparisons included in 'agricolae' are: kruskal(), waerden.test(), friedman() and durbin.test() (Conover, 1999).

The function kruskal() is used for N samples (N>2), populations or data coming from a completely random experiment (populations = treatments).

The function waerden.test(), similar to kruskal-wallis, uses a normal score instead of ranges as kruskal does.

The function friedman() is used for organoleptic evaluations of different products, made by judges (every judge evaluates all the products). It can also be used for the analysis of treatments of the randomized complete block design, where the response cannot be treated through the analysis of variance.

The function durbin.test() for the analysis of balanced incomplete block designs is very used for sampling tests, where the judges only evaluate a part of the treatments.

Montgomery book data (Montgomery, 2002) Included in the 'agricolae' package

For the examples, the 'agricolae' package data will be used.

5 STABILITY ANALYSIS

In 'agricolae' there are two methods for the study of stability and the AMMI model. These are: a parametric model for a simultaneous selection in yield and stability "SHUKLA'S STABILITY VARIANCE AND KANG'S", and a non-parametric method of Haynes, based on the data range.

5.1 PARAMETRIC STABILITY

Use the parametric model, function stability.par().

Prepare a data table where the rows and the columns are the genotypes and the environments, respectively. The data should correspond to yield averages or to another measured variable. Determine the variance of the common error for all the

environments and the number of repetitions that was evaluated for every genotype. If the repetitions are different, find a harmonious average that will represent the set. Finally, assign a name to each row that will represent the genotype. We will consider five environments in the following example:

```
\begin{array}{l} v1 <-c (10.2, 8.8, 8.8, 9.3, 9.6, 7.2, 8.4, 9.6, 7.9, 10, 9.3, 8.0, 10.1, 9.4, 10.8, 6.3, 7.4) \\ v2 <-c (7, 7.8, 7.0, 6.9, 7, 8.3, 7.4, 6.5, 6.8, 7.9, 7.3, 6.8, 8.1, 7.1, 7.1, 6.4, 4.1) \\ v3 <-c (5.3, 4.4, 5.3, 4.4, 5.5, 4.6, 6.2, 6.0, 6.5, 5.3, 5.7, 4.4, 4.2, 5.6, 5.8, 3.9, 3.8) \\ v4 <-c (7.8, 5.9, 7.3, 5.9, 7.8, 6.3, 7.9, 7.5, 7.6, 5.4, 5.6, 7.8, 6.5, 8.1, 7.5, 5.0, 5.4) \\ v5 <-c (9, 9.2, 8.8, 10.6, 8.3, 9.3, 9.6, 8.8, 7.9, 9.1, 7.7, 9.5, 9.4, 9.4, 10.3, 8.8, 8.7) \end{array}
```

For 17 genotypes, the identification is made by letters.

```
study <- data.frame(v1, v2, v3, v4, v5)
rownames(study) <- LETTERS[1:17]</pre>
```

An error variance of 2 and 4 repetitions is assumed.

```
stability <- stability.par(study, rep=4, MSerror=2)</pre>
```

0 5.88
          3.598500 ns 4.353030 ns 13.367031
```

The selected genotypes are: A, C, E, G, H, J, M, N and O. These genotypes have a higher yield and a lower variation. According to the ANOVA, the interaction is significant.

If for example there is an environmental index, it can be added as a covariate. For this case, the altitude of the localities is included.

```
altitude<-c(1200, 1300, 800, 1600, 2400)
stability <- stability.par(study,rep=4,MSerror=2, cova=TRUE,
name.cov= "altitude", file.cov= altitude)</pre>
```

5.2 NON-PARAMETRIC STABILITY

For non-parametric stability, the function in 'agricolae' is stability.nonpar(). The names of the genotypes should be included in the first column, and in the other columns, the response by environments.

5.3 AMMI

The model AMMI uses the biplot constructed through the principal components generated by the interaction environment-genotype. If there is such interaction, the percentage of the two principal components would explain more than the 50% of the total variation; in such case, the biplot would be a good alternative to study the interaction environment-genotype.

The data for AMMI should come from similar experiments conducted in different environments. Homogeneity of variance of the experimental error, produced in the different environments, is required. The analysis is done by combining the experiments.

The data can be organized in columns, thus: environment, genotype, repetition, and variable.

The data can also be the averages of the genotypes in each environment, but it is necessary to consider a harmonious average for the repetitions and a common variance of the error. The data should be organized in columns: environment, genotype, and variable.

When performing AMMI, this generates the BIPLOT graphics; see figure 5.1.

For the application, we consider the data used in the example of parametric stability (study):

```
par(mar=c(4,4,0,0))
rdto <- c(study[,1], study[,2], study[,3], study[,4], study[,5])</pre>
environment \leftarrow gl(5,17)
genotype <- rep(rownames(study),5)</pre>

```

Figure 5.1. Biplot and Triplot

In this case, the interaction is significant. The first two components explain 67.8%; then the biplot can provide information about the interaction genotype-environment. With the triplot, 90.3% would be explained.

6 SPECIAL FUNCTIONS

6.1 CONSENSUS OF DENDROGRAM

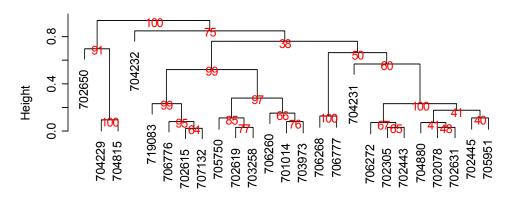

Consensus is the degree or similarity of the vertexes of a tree regarding its branches of the constructed dendrogram. The function to apply is consensus().

The data correspond to a table, with the name of the individuals and the variables in the rows and columns respectively. For the demonstration, we will use the "pamCIP" data of 'agricolae', which correspond to molecular markers of 43 entries of a germplasm bank (rows) and 107 markers (columns).

The program identifies duplicates in the rows and can operate in both cases. The result is a dendrogram, in which the consensus percentage is included, figure 6.1.

```
data(pamCIP)
rownames(pamCIP)<-substr(rownames(pamCIP),1,6)
par(cex=0.8)
output<-consensus(pamCIP,distance="binary", method="complete",
nboot=500)</pre>
```

Cluster Dendrogram

distancia hclust (*, "complete")

Figure 6.1. Dendrogram, production by consensus()

Duplicates: 18

New data : 25 Records

Consensus hclust

Method distance: binary
Method cluster : complete
rows and cols : 25 107
n-bootstrap : 500

Run time : 20.469 secs

When the dendrogram is complex, it is convenient to extract part of it with the function hcut(), figure 6.2.

hcut(output,h=0.4,group=8,type="t",edgePar = list(lty=1:2, col=2:1),main="group 8" ,col.text="blue",cex.text=1)

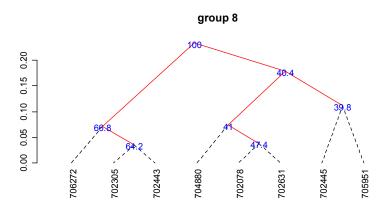

Figure 6.2. Dendrogram, production by hcut()

The obtained object "output" contains information about the process: names(output)

```
[1] "table.dend" "dendrogram" "duplicates"
```

This means that we can know the duplicates, reconstruct the tree diagram and maintain the interactions.

output\$table.dend

Reproduce the dendrogram:

```
dend<-output$dendrogram
data<-output$table.dend
plot(dend)
text(data[,3],data[,4],data[,5])</pre>
```

Construct a classic dendrogram, figure 6.3

```
dend<-as.dendrogram(output$dendrogram)
plot(dend,type="r",edgePar = list(lty=1:2, col=2:1))
text(data[,3],data[,4],data[,5],col="blue",cex=1)</pre>
```

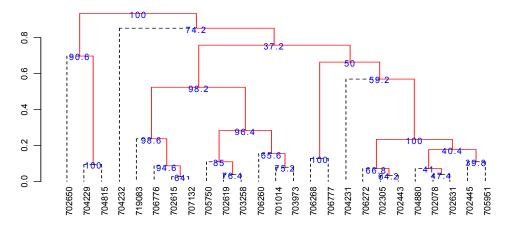

Figure 6.3. Classic dendrogram

6.2 MONTECARLO

It is a method for generating random numbers of an unknown distribution. It uses a data set and, through the cumulative behavior of its relative frequency, generates the possible random values that follow the data distribution. These new numbers are used in some simulation process.

The probability density of the original and simulated data can be compared, figure 6.4.

```
data(soil)
set.seed(9473)
simulated <- montecarlo(soil$pH,1000)</pre>
par(mar=c(3,0,2,1))
plot(density(soil$pH),axes=F,main="pH density of the soil\ncon
Ralstonia", xlab="", lwd=4)
lines(density(simulated), col="blue", lty=4,lwd=4)
h<-graph.freq(simulated,plot=F)</pre>
axis(1,0:12)
legend("topright",c("Original","Simulated"),lty=c(1,4),col=c("black"
, "blue"), lwd=4)
                          Densidad de pH del suelo
                               con Ralstonia
                                                     Original
                                                     Simulado
                                    6
                                                    10
                                                         11
```

Figure 6.4. Distribution of the simulated and the original data

1000 data have been generated, being the frequency table:

```

```

6.3 RE-SAMPLING IN LINEAR MODEL

It uses the permutation method for the calculation of the probabilities of the sources of variation of ANOVA according to the linear regression model or the design used. The principle is that the Y response does not depend on the averages proposed in the model; hence, the Y values can be permutated and many model estimates can be constructed. On the basis of the patterns of the random variables of the elements under study, the probability is calculated in order to measure the significance.

For a variance analysis, the data should be prepared similarly. The function to use is: resampling.model()

```
data(potato)
potato[,1]<-as.factor(potato[,1])</pre>
potato[,2]<-as.factor(potato[,2])</pre>
model<-"cutting~variety + date + variety:date"</pre>
analysis<-resampling.model(model, potato, k=1000)</pre>
Resampling of the experiments
_ _ _ _ _ _ _ _ _ _ _ _ _ _ _ _
Proposed model: cutting~variety + date + variety:date
Resampling of the analysis of variance for the proposed model
Determination of the P-Value by Resampling
Samples: 1000
           Df Sum Sq Mean Sq F value
                                                 Pr(>F) Resampling
            1 25.086806 25.086806 7.2580377 0.01952218 0.025
variety
             2 13.891758 6.945879 2.0095604 0.17670768
                                                             0.200
variety:date 2 4.853025 2.426513 0.7020312 0.51483592
                                                             0.530
Residuals 12 41.477005 3.456417
```

The function resampling.model() can be used when the errors have a different distribution from normal.

6.4 SIMULATION IN LINEAR MODEL

Under the assumption of normality, the function generates pseudo experimental errors under the proposed model, and determines the proportion of valid results according to the analysis of variance found.

The function is: simulation.model(). The data are prepared in a table, similarly to an analysis of variance.

Considering the example proposed in the previous procedure:

```
Response: cutting
           Df Sum Sq Mean Sq F value Pr(>F)
           1 25.087 25.087 7.2580 0.01952 *
variety
                     6.946 2.0096 0.17671
date
            2 13.892
variety:date 2 4.853
                     2.427 0.7020 0.51484
Residuals 12 41.477 3.456
Signif. codes: 0 '***' 0.001 '**' 0.01 '*' 0.05 '.' 0.1 '' 1
Validation of the analysis of variance for the proposed model
Simulations: 1000
            Df F value % Acceptance % Rejection Criterion
            1 7.2580377
                               51.5 48.5 acceptable
variety
date
             2 2.0095604
                               61.1
                                          38.9 acceptable
variety:date 2 0.7020312
                               67.5
                                          32.5 acceptable
```

The validation is referred to the percentage of decision results equal to the result of the ANOVA decision. Thus, 67.5% of the results simulated on the interaction variety*date gave the same result of acceptance or rejection obtained in the ANOVA.

6.5 PATH ANALYSIS

It corresponds to the "path analysis" method. The data correspond to correlation matrices of the independent ones with the dependent matrix (XY) and between the independent ones (XX).

It is necessary to assign names to the rows and columns in order to identify the direct and indirect effects.

```
corr.x < - matrix(c(1, 0.5, 0.5, 1), c(2, 2))
corr.y<- rbind(0.6,0.7)
names<-c("X1","X2")</pre>
dimnames(corr.x)<-list(names, names)</pre>
dimnames(corr.y)<-list(names, "Y")</pre>
output<-path.analysis(corr.x,corr.y)</pre>
Direct (Diagonal) and indirect effect path coefficients
______
X1 0.3333333 0.2666667
X2 0.1666667 0.5333333
Residual Effect^2 = 0.4266667
> output
$Coeff
         X1
X1 0.3333333 0.2666667
X2 0.1666667 0.5333333
$Residual
[1] 0.4266667
```

6.6 LINE X TESTER

It corresponds to a crossbreeding analysis of a genetic design. The data should be organized in a table. Only four columns are required: repetition, females, males, and response. In case it corresponds to progenitors, the females or males field will only be filled with the corresponding one. See the heterosis data.

```
Example with the heterosis data, locality 2.
    Replication
                Female Male v2

6.7 SOIL UNIFORMITY

The Smith index is an indicator of the uniformity, used to determine the parcel size for research purposes. The data correspond to a matrix or table that contains the response per basic unit, a number of n rows x m columns, and a total of n*m basic units.

For the test, we will use the rice file. The graphic is a result with the adjustment of a model for the parcel size and the coefficient of variation, figure 6.5.

```
data(rice)
table<-index.smith(rice,
main="Interaction between the CV and the parcel size" ,col="red",
type="l",xlab="Size")
uniformity <- data.frame(table$uniformity)</pre>

The size is the product of the width x the length of the parcel, and the rectangle size is the product of the width x the length.

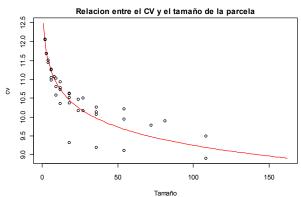

Figure 6.5. Adjustment curve for the optimal size of parcel

6.8 CONFIDENCE LIMITS IN BIODIVERSITY INDICES

The biodiversity indices are widely used for measuring the presence of living things in an ecological area. Many programs indicate their value. The function of 'agricolae' is also to show the confidence intervals, which can be used for a statistical comparison. Use the bootstrap procedure. The data are organized in a table; the species are placed in a column; and in another one, the number of individuals. The indices that can be calculated with the function index.bio() of 'agricolae' are: "Margalef", "Simpson.Dom", "Simpson.Div", "Berger.Parker", "McIntosh", and "Shannon."

In the example below, we will use the data obtained in the locality of Paracsho, district of Huasahuasi, province of Tarma in the department of Junín.

The evaluation was carried out in the parcels on 17 November 2005, without insecticide application. The counted specimens were the following:

```
data(paracsho)
species <- paracsho[79:87,4:6]
species</pre>
```

	Order	Family	Number.of.specimens
79	DIPTERA	TIPULIDAE	3
80	LEPIDOPTERA	NOCTUIDAE	1
81	NOCTUIDAE	PYRALIDAE	3
82	HEMIPTERA	ANTHOCORIDAE	1
83	DIPTERA	TACHINIDAE	16
84	DIPTERA	ANTHOCORIDAE	3
85	DIPTERA	SCATOPHAGIDAE	5
86	DIPTERA	SYRPHIDAE	1
87	DIPTERA	MUSCIDAE	3

The Shannon index is:

```
output <- index.bio(species[,3],method="Shannon",level=95,nboot=200)
Method: Shannon
Index: 3.52304
95 percent confidence interval:
    3.088775; 4.286088</pre>
```

6.9 CORRELATION

The function correlation() of 'agricolae' makes the correlations through the methods of Pearson, Spearman and Kendall for vectors and/or matrices. If they are two vectors, the test is carried out for one or two lines; if it is a matrix one, it determines the probabilities for a difference, whether it is greater or smaller.

For its application, consider the soil data: data(soil)

```
data(soil)
correlation(soil[,2:4],method="pearson")
Correlation Analysis
Method
         : pearson
Alternative: two.sided
$correlation

alternative hypothesis: true rho is not equal to 0
sample estimates:
cor
   0.7278362
```

6.10 OTHER FUNCTIONS

Desirability functions that facilitate the data management:

tapply.stat() Calculation of statesmen and mathematical operations in columns of a table in relation to grouped factors.

Factor and variable table

Application with 'agricolae' data:

```
data(RioChillon)
attach(RioChillon$babies)
tapply.stat(yield, farmer, function(x) max(x)-min(x))
detach (RioChillon$babies)
           farmer yield
1 AugustoZambrano 7.5
2
   Caballero 13.4
3
      ChocasAlto 14.1
      FelixAndia 19.4
4
5
     Huarangal-1 9.8
     Huarangal-2 9.1
6
7
     Huarangal-3 9.4
8
         Huatocay 19.4
9 IgnacioPolinario 13.1
```

It corresponds to the range of variation in the farmers' yield.

The function "tapply" can be used directly or with function.

If A is a table with columns 1,2 and 3 as factors, and 5,6 and 7 as variables, then the following procedures are valid:

```
tapply.stat(A[,5:7], A[,1:3], mean) tapply.stat(A[,5:7], A[,1:3], function(x) mean(x,na.rm=TRUE)) tapply.stat(A[,c(7,6)], A[,1:2], function(x) sd(x)*100/mean(x))
```

Coefficient of variation of an experiment

If "model" is the object resulting from an analysis of variance of the function aov() or Im() of R, then the function cv.model() calculates the coefficient of variation.

```
data(sweetpotato)
model <- model<-aov(yield ~ virus, data=sweetpotato)
cv.model(model)
[1] 17.16660</pre>
```

Skewness and curtosis

The skewness and curtosis results, obtained by 'agricolae', are equal to the ones obtained by SAS, MiniTab, SPSS, InfoStat, and Excel.

```
If x represents a data set:
> x<-c(3,4,5,2,3,4,5,6,4,NA,7)

skewness is calculated with:
> skewness(x)
[1] 0.3595431

and curtosis with:
> kurtosis(x)
[1]-0.1517996
```

Tabular value of Waller-Duncan

The function Waller determines the tabular value of Waller-Duncan. For the calculation, value F is necessary, calculated from the analysis of variance of the study factor, with its freedom degrees and the estimate of the variance of the experimental error. Value K, parameter of the function is the ratio between the two types of errors (I and II). To use it, a value associated with the alpha level is assigned. When the alpha level is 0.10, 50 is assigned to K; for 0.05, K=100; and for 0.01, K=500. K can take any value.

Figure 6.6 illustrates the function for different values of K with freedom degrees of 5 for the numerator and 15 for the denominator, and values of calculated F, equal to 2, 4, and 8.

```
q<-5
f<-15
K<-seq(10,1000,100)
n<-length(K)
y<-rep(0,3*n)
dim(y)<-c(n,3)
for(i in 1:n) y[i,1]<-waller(K[i],q,f,Fc=2)
for(i in 1:n) y[i,2]<-waller(K[i],q,f,Fc=4)
for(i in 1:n) y[i,3]<-waller(K[i],q,f,Fc=8)
plot(K,y[,1],type="l",col="blue",ylab="waller")
lines(K,y[,2],type="l",col="red",lty=2,lwd=2)
lines(K,y[,3],type="l",col="green",lty=4,lwd=2)
legend("topleft",c("2","4","8"),col=c("blue","red","green"),lty=c(1,8,20),lwd=2,title="Fc")
title(main="Waller in function of K")</pre>
```

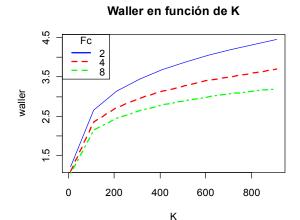

Figure 6.6. Function of Waller to different value of parameters K and Fc

AUDPC

The area under the disease progress curve (AUDPC), (see figure 6.7), calculates the absolute and relative progress of the disease. It is required to measure the disease in percentage terms during several dates, preferably equidistantly.

```
days<-c(7,14,21,28,35,42)
evaluation<-data.frame(E1=10,E2=40,E3=50,E4=70,E5=80,E6=90)
plot(days,
evaluation, type="h", ylim=c(0,100), axes=F, col="red", xlab="Days",
ylab="Evaluation")
lines(days, evaluation, col="red")
axis(1,days)
axis(2, seq(0, 100, 20), las=2)
abline(v=7, h=100, lty=4, lwd=2, col="blue")
abline (v=42, h=0, lty=4, lwd=2, col="blue")
audpc(evaluation,days)
audpc(evaluation,days,"relative")
text(15,80,"Audpc Absolute = 2030")
text(15,70,"Audpc Relative = 0.58")
           100
                    Audpc Absoluta = 2030
            80
                    Audpc Relativa = 0.58
        Evaluación
            60
            40
            20
             0
                  7
                           14
                                     21
                                              28
                                                        35
                                                                 42
```

Días Figure 6.7. AUDPC: Area under the curve

NON-ADDITIVITY

Tukey's test for non-additivity is used when there are doubts about the additivity veracity of a model. This test confirms such assumption and it is expected to accept the null hypothesis of the non-additive effect of the model.

For this test, all the experimental data used in the estimation of the linear additive model are required.

Use the function nonadditivity() of 'agricolae'. For its demonstration, the experimental data "potato", of the package 'agricolae', will be used. In this case, the model corresponds to the randomized complete block design, where the treatments are the varieties.

```
data(potato)
potato[,1]<-as.factor(potato[,1])</pre>
model<-lm(cutting ~ date + variety,potato)</pre>
df<-df.residual(model)</pre>
MSerror<-deviance(model)/df
attach (potato)
analysis<-nonadditivity(cutting, date, variety, df, MSerror)</pre>
detach (potato)
Tukey's test of non-additivity
cutting
P: 15.37166
Q: 77.4444
Analysis of Variance Table
Response: residual
              Df Sum Sq Mean Sq F value Pr(>F)
Non-additivity 1 3.051 3.051
                                  0.922 0.3532
Residuals
             14 46.330
                           3.309
```

According to the results, the model is additive because the p.value 0.35 is greater than 0.05.
